MySQL Reference Manual

Table of Contents

List of Tables

List of Examples

Preface

This is the Reference Manual for the MySQL Database System. It documents MySQL up to Version 5.0.11-beta, but is also applicable for older versions of the MySQL software (such as 3.23 or 4.0-production) because functional changes are indicated with reference to a version number.

Chapter 1. General Information

The MySQL® software delivers a very fast, multi-threaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. MySQL is a registered trademark of MySQL AB.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (http://www.fsf.org/licenses/) or can purchase a standard commercial license from MySQL AB. See http://www.mysql.com/company/legal/licensing/ for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion about the capabilities of the MySQL Database Server, see Section 1.4.2, "The Main Features of MySQL".

- For installation instructions, see Chapter 2, *Installing MySQL*.

- For tips on porting the MySQL Database Software to new architectures or operating systems, see Appendix F, *Porting to Other Systems*.

- For information about upgrading from a Version 4.1 release, see Section 2.10.2, "Upgrading from Version 4.1 to 5.0".

- For information about upgrading from a Version 4.0 release, see Section 2.10.3, "Upgrading from Version 4.0 to 4.1".

- For information about upgrading from a Version 3.23 release, see Section 2.10.4, "Upgrading from Version 3.23 to 4.0".

- For a tutorial introduction to the MySQL Database Server, see Chapter 3, *MySQL Tutorial*.

- For examples of SQL and benchmarking information, see the benchmarking directory (`sql-bench` in the distribution).

- For a history of new features and bugfixes, see Appendix E, *MySQL Change History*.

- For a list of currently known bugs and misfeatures, see Section A.8, "Known Issues in MySQL".

- For future plans, see Appendix D, *MySQL and the Future (the TODO)*.

- For a list of all the contributors to this project, see Appendix C, *Credits*.

Important:

Reports of errors (often called "bugs"), as well as questions and comments, should be sent to http://bugs.mysql.com. See Section 1.7.1.3, "How to Report Bugs or Problems".

If you have found a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to `<security@mysql.com>`.

1.1. About This Manual

This is the Reference Manual for all releases of the MySQL Database System through Version 5.0.11-beta. It is also applicable for all previous versions of the MySQL software (such as 3.23 or 4.0) because functional changes are indicated with reference to version numbers. Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at http://dev.mysql.com/doc/. Other formats also are available, including HTML, PDF, and Windows CHM versions.

The primary document is a set of DocBook [http://docbook.org/] XML files. The HTML version and other formats are produced automatically using, among other tools, the DocBook XSL stylesheets [http://docbook.sourceforge.net/release/xsl/current/doc/reference.html].

If you have any suggestions concerning additions or corrections to this manual, please send them to the documentation team at `<docs@mysql.com>`.

This manual was initially written by David Axmark and Michael "Monty" Widenius. It is maintained by the MySQL Documentation Team, consisting of Paul DuBois, Stefan Hinz, Mike Hillyer, and Jon Stephens. For the many other contributors, see Appendix C, *Credits*.

The copyright to this manual is owned by the Swedish company MySQL AB. MySQL® and the MySQL logo are registered trademarks of MySQL AB. Other trademarks and registered trademarks referred to in this manual are the property of their respective owners, and are used for identification purposes only.

1.2. Conventions Used in This Manual

This manual uses certain typographical conventions:

- `Text in this style` is used for SQL statements; database, table, and column names; C and Perl code; and environment variables. Example: "To reload the grant tables, use the `FLUSH PRIVILEGES` statement".

  Text in this style is used to indicate input that you type in examples.

- `Text in this style` is used to indicate the names of executable programs and scripts, examples being `mysql` (the MySQL command line client program) and `mysqld` (the MySQL server executable).

- *`Text in this style`* is used for variable input for which you should substitute a value of your own choosing.

- Filenames and directory names are written like this: "The global `my.cnf` file is located in the `/etc` directory".

- Character sequences are written like this: "To specify a wildcard, use the '`%`' character".

- *Text in this style* is used for emphasis.

- **Text in this style** is used in table headings and to convey especially strong emphasis.

When commands are shown that are meant to be executed from within a particular program, the program is indicated by a prompt shown before the command. For example, `shell>` indicates a command that you execute from your login shell, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
mysql> type a mysql statement here
```

The "shell" is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the

example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses *db_name*, *tbl_name*, and *col_name*. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case sensitive and may be written in uppercase or lowercase. This manual uses uppercase.

In syntax descriptions, square brackets ('[' and ']') are used to indicate optional words or clauses. For example, in the following statement, IF EXISTS is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars ('|'). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets ('[' and ']'):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces ('{' and '}'):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (...) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, INSERT ... SELECT is shorthand for the form of INSERT statement that is followed by a SELECT statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple *reset_option* values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set an environment variable and run a command looks like this in Bourne shell syntax:

```
shell> VARNAME=value some_command
```

If you are using csh or tcsh, you must issue commands somewhat differently. You would execute the sequence just shown like this:

```
shell> setenv VARNAME value
shell> some_command
```

1.3. Overview of MySQL AB

MySQL AB is the company of the MySQL founders and main developers. MySQL AB was origin-

ally established in Sweden by David Axmark, Allan Larsson, and Michael "Monty" Widenius.

We are dedicated to developing the MySQL database software and promoting it to new users. MySQL AB owns the copyright to the MySQL source code, the MySQL logo and (registered) trademark, and this manual. See Section 1.4, "Overview of the MySQL Database Management System".

The MySQL core values show our dedication to MySQL and Open Source.

These core values direct how MySQL AB works with the MySQL server software:

- To be the best and the most widely used database in the world

- To be available and affordable by all

- To be easy to use

- To be continuously improved while remaining fast and safe

- To be fun to use and improve

- To be free from bugs

These are the core values of the company MySQL AB and its employees:

- We subscribe to the Open Source philosophy and support the Open Source community

- We aim to be good citizens

- We prefer partners that share our values and mindset

- We answer email and provide support

- We are a virtual company, networking with others

- We work against software patents

The MySQL Web site (http://www.mysql.com/) provides the latest information about MySQL and MySQL AB.

By the way, the "AB" part of the company name is the acronym for the Swedish "aktiebolag," or "stock company." It translates to "MySQL, Inc." In fact, MySQL, Inc. and MySQL GmbH are examples of MySQL AB subsidiaries. They are located in the US and Germany, respectively.

1.4. Overview of the MySQL Database Management System

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by MySQL AB. MySQL AB is a commercial company, founded by the MySQL developers. It is a second generation Open Source company that unites Open Source values and methodology with a successful business model.

The MySQL Web site (http://www.mysql.com/) provides the latest information about MySQL software and MySQL AB.

- MySQL is a database management system.

    A database is a structured collection of data. It may be anything from a simple shopping list to a

picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities or as parts of other applications.

- MySQL is a relational database management system.

  A relational database stores data in separate tables rather than putting all the data in one big storeroom. This adds speed and flexibility. The SQL part of "MySQL" stands for "Structured Query Language." SQL is the most common standardized language used to access databases and is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, "SQL-92" refers to the standard released in 1992, "SQL:1999" refers to the standard released in 1999, and "SQL:2003" refers to the current version of the standard. We use the phrase "the SQL standard" to mean the current version of the SQL Standard at any time.

- MySQL software is Open Source.

  Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), http://www.fsf.org/licenses/, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (http://www.mysql.com/company/legal/licensing/).

- The MySQL Database Server is very fast, reliable, and easy to use.

  If that is what you are looking for, you should give it a try. MySQL Server also has a practical set of features developed in close cooperation with our users. You can find a performance comparison of MySQL Server with other database managers on our benchmark page. See Section 7.1.4, "The MySQL Benchmark Suite".

  MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- MySQL Server works in client/server or embedded systems.

  The MySQL Database Software is a client/server system that consists of a multi-threaded SQL server that supports different backends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

  We also provide MySQL Server as an embedded multi-threaded library that you can link into your application to get a smaller, faster, easier-to-manage product.

- A large amount of contributed MySQL software is available.

  It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce "MySQL" is "My Ess Que Ell" (not "my sequel"), but we don't mind if you pronounce it as "my sequel" or in some other localized way.

1.4.1. History of MySQL

We started out with the intention of using `mSQL` to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that `mSQL` was not

fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as mSQL. This API was designed to allow third-party code that was written for use with mSQL to be ported easily for use with MySQL.

The derivation of the name MySQL is not clear. Our base directory and a large number of our libraries and tools have had the prefix "my" for well over 10 years. However, co-founder Monty Widenius's daughter is also named My. Which of the two gave its name to MySQL is still a mystery, even for us.

The name of the MySQL Dolphin (our logo) is "Sakila," which was chosen by the founders of MySQL AB from a huge list of names suggested by users in our "Name the Dolphin" contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

1.4.2. The Main Features of MySQL

The following list describes some of the important characteristics of the MySQL Database Software. See also Section 1.6, "MySQL Development Roadmap" for more information about current and upcoming features.

- Internals and Portability

  - Written in C and C++.

  - Tested with a broad range of different compilers.

  - Works on many different platforms. See Section 2.1.1, "Operating Systems Supported by MySQL".

  - Uses GNU Automake, Autoconf, and Libtool for portability.

  - APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available. See Chapter 23, *MySQL APIs and Libraries*.

  - Fully multi-threaded using kernel threads. It can easily use multiple CPUs if they are available.

  - Provides transactional and non-transactional storage engines.

  - Uses very fast B-tree disk tables (MyISAM) with index compression.

  - Relatively easy to add another storage engine. This is useful if you want to add an SQL interface to an in-house database.

  - A very fast thread-based memory allocation system.

  - Very fast joins using an optimized one-sweep multi-join.

  - In-memory hash tables, which are used as temporary tables.

  - SQL functions are implemented using a highly optimized class library and should be as fast as possible. Usually there is no memory allocation at all after query initialization.

  - The MySQL code is tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (http://developer.kde.org/~sewardj/).

  - The server is available as a separate program for use in a client/server networked environment. It is also available as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

- Column Types

  - Many column types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, `FLOAT`, `DOUBLE`, `CHAR`, `VARCHAR`, `TEXT`, `BLOB`, `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, `YEAR`, `SET`, `ENUM`, and OpenGIS spatial types. See Chapter 11, *Column Types*.

  - Fixed-length and variable-length records.

- Statements and Functions

  - Full operator and function support in the `SELECT` and `WHERE` clauses of queries. For example:

    ```
    mysql> SELECT CONCAT(first_name, ' ', last_name)
        -> FROM citizen
        -> WHERE income/dependents > 10000 AND age > 30;
    ```

  - Full support for SQL `GROUP BY` and `ORDER BY` clauses. Support for group functions (`COUNT()`, `COUNT(DISTINCT ...)`, `AVG()`, `STD()`, `SUM()`, `MAX()`, `MIN()`, and `GROUP_CONCAT()`).

  - Support for `LEFT OUTER JOIN` and `RIGHT OUTER JOIN` with both standard SQL and ODBC syntax.

  - Support for aliases on tables and columns as required by standard SQL.

  - `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` return the number of rows that were changed (affected). It is possible to return the number of rows matched instead by setting a flag when connecting to the server.

  - The MySQL-specific `SHOW` command can be used to retrieve information about databases, database engines, tables, and indexes. The `EXPLAIN` command can be used to determine how the optimizer resolves a query.

  - Function names do not clash with table or column names. For example, `ABS` is a valid column name. The only restriction is that for a function call, no spaces are allowed between the function name and the '(' that follows it. See Section 9.6, "Treatment of Reserved Words in MySQL".

  - You can mix tables from different databases in the same query (as of MySQL 3.22).

- Security

  - A privilege and password system that is very flexible and secure, and that allows host-based verification. Passwords are secure because all password traffic is encrypted when you connect to a server.

- Scalability and Limits

  - Handles large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 60,000 tables and about 5,000,000,000 rows.

  - Up to 64 indexes per table are allowed (32 before MySQL 4.1.2). Each index may consist of 1 to 16 columns or parts of columns. The maximum index width is 1000 bytes (500 before MySQL 4.1.2). An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

- Connectivity

  - Clients can connect to the MySQL server using TCP/IP sockets on any platform. On Windows systems in the NT family (NT, 2000, XP, or 2003), clients can connect using named pipes. On Unix systems, clients can connect using Unix domain socket files.

- In MySQL versions 4.1 and higher, Windows servers also support shared-memory connections if started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=memory` option.

- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. MyODBC source is available. All ODBC 2.5 functions are supported, as are many others. See Chapter 24, *MySQL Connectors*.

- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See Chapter 24, *MySQL Connectors*.

- Localization

  - The server can provide error messages to clients in many languages. See Section 5.9.2, "Setting the Error Message Language".

  - Full support for several different character sets, including `latin1` (cp1252), `german`, `big5`, `ujis`, and more. For example, the Scandinavian characters 'å', 'ä' and 'ö' are allowed in table and column names. Unicode support is available as of MySQL 4.1.

  - All data is saved in the chosen character set. All comparisons for normal string columns are case-insensitive.

  - Sorting is done according to the chosen character set (using Swedish collation by default). It is possible to change this when the MySQL server is started. To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.

- Clients and Tools

  - The MySQL server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on `MyISAM` tables. See Chapter 5, *Database Administration*.

  - All MySQL programs can be invoked with the `--help` or `-?` options to obtain online assistance.

1.4.3. MySQL Stability

This section addresses the questions, "*How stable is MySQL Server?*" and, "*Can I depend on MySQL Server in this project?*" We will try to clarify these issues and answer some important questions that concern many potential users. The information in this section is based on data gathered from the mailing lists, which are very active in identifying problems as well as reporting types of use.

The original code stems back to the early 1980s. It provides a stable code base, and the ISAM table format used by the original storage engine remains backward-compatible. At TcX, the predecessor of MySQL AB, MySQL code has worked in projects since mid-1996, without any problems. When the MySQL Database Software initially was released to a wider public, our new users quickly found some pieces of untested code. Each new release since then has had fewer portability problems, even though each new release has also had many new features.

Each release of the MySQL Server has been usable. Problems have occurred only when users try code from the "gray zones." Naturally, new users don't know what the gray zones are; this section therefore attempts to document those areas that are currently known. The descriptions mostly deal with Versions 3.23 and later of MySQL Server. All known and reported bugs are fixed in the latest version, with the exception of those listed in the bugs section, which are design-related. See Sec-

tion A.8, "Known Issues in MySQL".

The MySQL Server design is multi-layered with independent modules. Some of the newer modules are listed here with an indication of how well-tested each of them is:

- Replication (Stable)

  Large groups of servers using replication are in production use, with good results. Work on enhanced replication features is continuing in MySQL 5.x.

- `InnoDB` tables (Stable)

  The `InnoDB` transactional storage engine has been stable since version 3.23.49. `InnoDB` is being used in large, heavy-load production systems.

- `BDB` tables (Stable)

  The `Berkeley DB` code is very stable, but we are still improving the `BDB` transactional storage engine interface in MySQL Server.

- Full-text searches (Stable)

  Full-text searching is widely used. Important feature enhancements were added in MySQL 4.0 and 4.1.

- `MyODBC` 3.51 (Stable)

  `MyODBC` 3.51 uses ODBC SDK 3.51 and is in wide production use. Some issues brought up appear to be application-related and independent of the ODBC driver or underlying database server.

1.4.4. How Big MySQL Tables Can Be

MySQL 3.22 had a 4GB (4 gigabyte) limit on table size. With the `MyISAM` storage engine in MySQL 3.23, the maximum table size was increased to 65536 terabytes ($256^7 - 1$ bytes). With this larger allowed table size, the maximum effective table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits.

The `InnoDB` storage engine maintains `InnoDB` tables within a tablespace that can be created from several files. This allows a table to exceed the maximum individual file size. The tablespace can include raw disk partitions, which allows extremely large tables. The maximum tablespace size is 64TB.

The following table lists some examples of operating system file-size limits. This is only a rough guide and is not intended to be definitive. For the most up-to-date information, be sure to check the documentation specific to your operating system.

Operating System	File-size Limit
Linux 2.2-Intel 32-bit	2GB (LFS: 4GB)
Linux 2.4+	(using ext3 filesystem) 4TB
Solaris 9/10	16TB
NetWare w/NSS filesystem	8TB
win32 w/ FAT/FAT32	2GB/4GB
win32 w/ NTFS	2TB (possibly larger)
MacOS X w/ HFS+	2TB

On Linux 2.2, you can get `MyISAM` tables larger than 2GB in size by using the Large File Support (LFS) patch for the ext2 filesystem. On Linux 2.4, patches also exist for ReiserFS to get support for

big files (up to 2TB). Most current Linux distributions are based on kernel 2.4 and include all the required LFS patches. With JFS and XFS, petabyte and larger files are possible on Linux. However, the maximum available file size still depends on several factors, one of them being the filesystem used to store MySQL tables.

For a detailed overview about LFS in Linux, have a look at Andreas Jaeger's *Large File Support in Linux* page at http://www.suse.de/~aj/linux_lfs.html.

Windows users please note: FAT and VFAT (FAT32) are *not* considered suitable for production use with MySQL. Use NTFS instead.

By default, MySQL creates `MyISAM` tables with an internal structure that allows a maximum size of about 4GB. You can check the maximum table size for a table with the `SHOW TABLE STATUS` statement or with `myisamchk -dv` `tbl_name`. See Section 13.5.4, "`SHOW` Syntax".

If you need a `MyISAM` table that is larger than 4GB in size (and your operating system supports large files), the `CREATE TABLE` statement allows `AVG_ROW_LENGTH` and `MAX_ROWS` options. See Section 13.1.5, "`CREATE TABLE` Syntax". You can also change these options with `ALTER TABLE` after the table has been created, to increase the table's maximum allowable size. See Section 13.1.2, "`ALTER TABLE` Syntax".

Other ways to work around file-size limits for `MyISAM` tables are as follows:

- If your large table is read-only, you can use `myisampack` to compress it. `myisampack` usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. `myisampack` also can merge multiple tables into a single table. See Section 8.2, "myisampack — Generate Compressed, Read-Only MyISAM Tables".

- MySQL includes a `MERGE` library that allows you to handle a collection of `MyISAM` tables that have identical structure as a single `MERGE` table. See Section 14.2, "The `MERGE` Storage Engine".

1.4.5. Year 2000 Compliance

The MySQL Server itself has no problems with Year 2000 (Y2K) compliance:

- MySQL Server uses Unix time functions that handle dates into the year `2037` for `TIMESTAMP` values. For `DATE` and `DATETIME` values, dates through the year `9999` are accepted.

- All MySQL date functions are implemented in one source file, `sql/time.cc`, and are coded very carefully to be year 2000-safe.

- In MySQL 3.22 and later, the `YEAR` column type can store the years `0` and `1901` to `2155` in one byte and display them using two or four digits. All two-digit years are considered to be in the range `1970` to `2069`, which means that if you store `01` in a `YEAR` column, MySQL Server treats it as `2001`.

The following simple demonstration illustrates that MySQL Server has no problems with `DATE` or `DATETIME` values through the year 9999, and no problems with `TIMESTAMP` values until after the year 2030:

```
mysql> DROP TABLE IF EXISTS y2k;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE y2k (date DATE,
    ->                    date_time DATETIME,
    ->                    time_stamp TIMESTAMP);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO y2k VALUES
    -> ('1998-12-31','1998-12-31 23:59:59',19981231235959),
```

```
    -> ('1999-01-01','1999-01-01 00:00:00',19990101000000),
    -> ('1999-09-09','1999-09-09 23:59:59',19990909235959),
    -> ('2000-01-01','2000-01-01 00:00:00',20000101000000),
    -> ('2000-02-28','2000-02-28 00:00:00',20000228000000),
    -> ('2000-02-29','2000-02-29 00:00:00',20000229000000),
    -> ('2000-03-01','2000-03-01 00:00:00',20000301000000),
    -> ('2000-12-31','2000-12-31 23:59:59',20001231235959),
    -> ('2001-01-01','2001-01-01 00:00:00',20010101000000),
    -> ('2004-12-31','2004-12-31 23:59:59',20041231235959),
    -> ('2005-01-01','2005-01-01 00:00:00',20050101000000),
    -> ('2030-01-01','2030-01-01 00:00:00',20300101000000),
    -> ('2040-01-01','2040-01-01 00:00:00',20400101000000),
    -> ('9999-12-31','9999-12-31 23:59:59',99991231235959);
Query OK, 14 rows affected (0.01 sec)
Records: 14  Duplicates: 0  Warnings: 2

mysql> SELECT * FROM y2k;
+------------+---------------------+----------------+
| date       | date_time           | time_stamp     |
+------------+---------------------+----------------+

14 rows in set (0.00 sec)
```

The final two TIMESTAMP column values are zero because the year values (2040, 9999) exceed the TIMESTAMP maximum. The TIMESTAMP data type, which is used to store the current time, supports values that range from 19700101000000 to 20300101000000 on 32-bit machines (signed value). On 64-bit machines, TIMESTAMP handles values up to 2106 (unsigned value).

Although MySQL Server itself is Y2K-safe, you may run into problems if you use it with applications that are not Y2K-safe. For example, many old applications store or manipulate years using two-digit values (which are ambiguous) rather than four-digit values. This problem may be compounded by applications that use values such as 00 or 99 as "missing" value indicators. Unfortunately, these problems may be difficult to fix because different applications may be written by different programmers, each of whom may use a different set of conventions and date-handling functions.

Thus, even though MySQL Server has no Y2K problems, *it is the application's responsibility to provide unambiguous input*. See Section 11.3.4, "Y2K Issues and Date Types" for MySQL Server's rules for dealing with ambiguous date input data that contains two-digit year values.

1.5. Overview of the MaxDB Database Management System

MaxDB is an enterprise-level database. MaxDB is the new name of a database management system formerly called SAP DB.

1.5.1. History of MaxDB

The history of MaxDB goes back to SAP DB, SAP AG's DBMS, i.e. MaxDB is a re-branded and

enhanced version of SAP DB. For many years, MaxDB has been used for small, medium, and large installations of the mySAP Business Suite and other demanding SQL applications requiring an enterprise-class DBMS with regard to the number of users, the transactional workload, and the size of the database.

SAP DB was meant to provide an alternative to third-party database systems such as Oracle, Microsoft SQL Server, and DB2 by IBM. In October 2000, SAP AG released SAP DB under the GNU GPL license (see Appendix J, *GNU General Public License*), thus making it open source software.

Today, MaxDB is used in about 3,500 SAP customer installations worldwide. Moreover, the majority of all DBMS installations on Unix and Linux within SAP's IT department rely on MaxDB. MaxDB is tuned towards heavy-duty online transaction processing (OLTP) with several thousand users and database sizes ranging from several hundred GB to multiple TB.

In 2003 SAP and MySQL concluded a partnership and development cooperation agreement. As a result, SAP's database system SAP DB has been delivered under the name of MaxDB by MySQL since the release of version 7.5 (November 2003).

Version 7.5 of MaxDB is a direct advancement of the SAP DB 7.4 code base. Therefore, the MaxDB software version 7.5 can be used as a direct upgrade of previous SAP DB versions starting 7.2.04 and higher.

Now, as before, the former SAP DB development team at SAP AG is responsible for developing and supporting MaxDB. Both SAP AG and MySQL AB handle the sale and distribution of MaxDB. The advancement of MaxDB and the MySQL Server leverages synergies that benefit both product lines.

MaxDB is subjected to SAP AG's complete quality assurance process before it is shipped with SAP solutions or provided as a download from the MySQL site.

1.5.2. Licensing and Support

MaxDB can be used under the same licenses available for the other products distributed by MySQL AB. Thus, MaxDB is available under the GNU General Public License, and a commercial license. For more information on licensing, see http://www.mysql.com/company/legal/licensing/.

MySQL offers MaxDB support to non-SAP customers.

1.5.3. MaxDB-Related Links

The main page for information about MaxDB is http://www.mysql.com/products/maxdb. Information formerly available at http://www.sapdb.org is only related to releases 7.3 and 7.4 and is no longer maintained.

1.5.4. Basic Concepts of MaxDB

MaxDB operates as a client/server product. It was developed to meet the needs of installations in OLTP and Data Warehouse/OLAP/Decision Support scenarios. **Benefits:**

- **Easy configuration and administration:** GUI-based Installation Manager and Database Manager as single admin tools for DBMS operations

- **Around-the-clock operation, no planned downtimes, no permanent attendance required:** Automatic space management, no need for reorganizations

- **Elaborate backup and restore capabilities:** Online and incremental backups, recovery wizard to guide you through the recovery scenario

- **Supports large number of users, database sizes in the terabytes, and demanding workloads:** Proven reliability, performance, and scalability

- **High availability:** Cluster support, standby configuration, hot standby configuration

1.5.5. Feature Differences Between MaxDB and MySQL

The following list provides a short summary of the main differences between MaxDB and MySQL; it is not complete.

- MaxDB runs as a client/server system. MySQL can run as a client/server system or as an embedded system.

- MaxDB might not run on all platforms supported by MySQL. For example, MaxDB does not run on IBM's OS/2.

- MaxDB uses a proprietary network protocol for client/server communication. MySQL uses TCP/IP (with or without SSL encryption), sockets (under Unix-like systems), or named pipes (under Windows NT-family systems).

- MaxDB supports stored procedures. For MySQL, stored procedures are implemented in version 5.0. MaxDB also supports programming of triggers through an SQL extension, which are also implemented in MySQL 5.0. MaxDB contains a debugger for stored procedure languages, can cascade nested triggers, and supports multiple triggers per action and row.

- MaxDB is distributed with user interfaces that are text-based, graphical, or Web-based. MySQL is distributed with text-based user interfaces only; graphical user interface (MySQL Query Browser, MySQL Administrator) are shipped separately from the main distributions. Web-based user interfaces for MySQL are offered by third parties.

- MaxDB supports a number of programming interfaces that also are supported by MySQL. For developing with MaxDB, the MaxDB ODBC Driver, SQL Database Connectivity (SQLDBC), JDBC Driver, Perl and Python modules and a MaxDB PHP extension, which provides access to the MySQL MaxDB databases using PHP, are available. Third Party Programming Interfaces: Support for OLE DB, ADO, DAO, RDO and .NET through ODBC. MaxDB supports embedded SQL with C/C++.

- MaxDB includes administrative features that MySQL does not have: job scheduling by time, event, and alert, and sending messages to a database administrator on alert thresholds.

1.5.6. Interoperability Features Between MaxDB and MySQL

The MaxDB Synchronization Manager was released as part of MaxDB 7.6. The Synchronization Manager supports creation of asynchronous replication scenarios between several MaxDB instances. However, interoperability features also are planned, so that the Synchronization Manager supports replication to and from a MySQL server.

In the first release, the Synchronization Manager supports inserting data into MySQL. This means that initially only replication from MaxDB to MySQL is supported. In the course of 2005, exporting of data from a MySQL server to the Synchronization Manager will be added, thus adding support for MySQL to MaxDB replication scenarios.

MaxDB 7.6, with the Synchronization Manager, was released as a beta version in January 2005.

1.5.7. Reserved Words in MaxDB

Like MySQL, MaxDB has a number of reserved words that have special meanings. Normally, they cannot be used as names of identifiers, such as database or table names. The following table lists reserved words in MaxDB, indicates the context in which those words are used, and indicates whether or not they have counterparts in MySQL. If such a counterpart exists, the meaning in MySQL might

be identical or differing in some aspects. The main purpose is to list in which respects MaxDB differs from MySQL; therefore, this list is not complete.

For the list of reserved words in MySQL, see Section 9.6, "Treatment of Reserved Words in MySQL".

Reserved in MaxDB	Context of usage in MaxDB	MySQL counterpart
@	Can prefix identifier, like "@table"	Not allowed
ADDDATE()	SQL function	ADDDATE(); added in MySQL 4.1.1
ADDTIME()	SQL function	ADDTIME(); added in MySQL 4.1.1
ALPHA	SQL function	Nothing comparable
ARRAY	Data type	Not implemented
ASCII()	SQL function	ASCII(), but implemented with a different meaning
AUTOCOMMIT	Transactions; ON by default	Transactions; OFF by default
BOOLEAN	Column types; BOOLEAN accepts as values only TRUE, FALSE, and NULL	BOOLEAN was added in MySQL 4.1.0; it is a synonym for BOOL which is mapped to TINYINT(1). It accepts integer values in the same range as TINYINT as well as NULL. TRUE and FALSE can be used as aliases for 1 and 0.
CHECK	CHECK TABLE	CHECK TABLE; similar, but not identical usage
COLUMN	Column types	COLUMN; noise word
CHAR()	SQL function	CHAR(); identical syntax; similar, not identical usage
COMMIT	Implicit commits of transactions happen when data definition statements are issued	Implicit commits of transactions happen when data definition statements are issued, and also with a number of other statements
COSH()	SQL function	Nothing comparable
COT()	SQL function	COT(); identical syntax and implementation
CREATE	SQL, data definition language	CREATE
DATABASE	SQL function	DATABASE(); DATABASE is used in a different context; for example, CREATE DATABASE
DATE()	SQL function	CURRENT_DATE
DATEDIFF()	SQL function	DATEDIFF(); added in MySQL 4.1.1
DAY()	SQL function	Nothing comparable
DAYOFWEEK()	SQL function	DAYOFWEEK(); by default, 1 represents Monday in MaxDB and Sunday in MySQL
DISTINCT	SQL functions AVG, MAX, MIN, SUM	DISTINCT; but used in a different context: SELECT DISTINCT
DROP	DROP INDEX, for example	DROP INDEX; similar, but not identical usage
EBCDIC()	SQL function	Nothing comparable
EXPAND()	SQL function	Nothing comparable
EXPLAIN	Optimization	EXPLAIN; similar, but not identical usage
FIXED()	SQL function	Nothing comparable
FLOAT()	SQL function	Nothing comparable
HEX()	SQL function	HEX(); similar, but not identical usage
INDEX()	SQL function	INSTR() or LOCATE(); similar, but not

		identical syntaxes and meanings
INDEX	USE INDEX, IGNORE INDEX and similar hints are used right after SELECT; for example, SELECT ... USE INDEX	USE INDEX, IGNORE INDEX and similar hints are used in the FROM clause of a SELECT query; for example, in SELECT ... FROM ... USE INDEX
INITCAP()	SQL function	Nothing comparable
LENGTH()	SQL function	LENGTH(); identical syntax, but slightly different implementation
LFILL()	SQL function	Nothing comparable
LIKE	Comparisons	LIKE; but the extended LIKE MaxDB provides rather resembles the MySQL REGEX
LIKE wildcards	MaxDB supports "%", "_", "Control-underline", "Control-up arrow", "*", and "?" as wildcards in LIKE comparisons	MySQL supports "%", and "_" as wildcards in LIKE comparisons
LPAD()	SQL function	LPAD(); slightly different implementation
LTRIM()	SQL function	LTRIM(); slightly different implementation
MAKEDATE()	SQL function	MAKEDATE(); added in MySQL 4.1.1
MAKETIME()	SQL function	MAKETIME(); added in MySQL 4.1.1
MAPCHAR()	SQL function	Nothing comparable
MICRO-SECOND()	SQL function	MICROSECOND(); added in MySQL 4.1.1
NOROUND()	SQL function	Nothing comparable
NULL	Column types; comparisons	NULL; MaxDB supports special NULL values that are returned by arithmetic operations that lead to an overflow or a division by zero; MySQL does not support such special values
PI	SQL function	PI(); identical syntax and implementation, but parentheses are mandatory in MySQL
REF	Data type	Nothing comparable
RFILL()	SQL function	Nothing comparable
ROWNO	Predicate in WHERE clause	Similar to LIMIT clause
RPAD()	SQL function	RPAD(); slightly different implementation
RTRIM()	SQL function	RTRIM(); slightly different implementation
SEQUENCE	CREATE SEQUENCE, DROP SEQUENCE	AUTO_INCREMENT; similar concept, but different implementation
SINH()	SQL function	Nothing comparable
SOUNDS()	SQL function	SOUNDEX(); slightly different syntax
STATISTICS	UPDATE STATISTICS	ANALYZE TABLE; similar concept, but different implementation
SUBSTR()	SQL function	SUBSTRING(); slightly different implementation
SUBTIME()	SQL function	SUBTIME(); added in MySQL 4.1.1
SYNONYM	Data definition language: CREATE [PUBLIC] SYNONYM, RENAME SYNONYM, DROP SYNONYM	Nothing comparable
TANH()	SQL function	Nothing comparable
TIME()	SQL function	CURRENT_TIME

`TIMEDIFF()`	SQL function	`TIMEDIFF()`; added in MySQL 4.1.1
`TIMESTAMP()`	SQL function	`TIMESTAMP()`; added in MySQL 4.1.1
`TIMESTAMP()` as argument to `DAYOFMONTH()` and `DAY-OFYEAR()`	SQL function	Nothing comparable
`TIMEZONE()`	SQL function	Nothing comparable
`TRANSAC-TION()`	Returns the ID of the current transaction	Nothing comparable
`TRANSLATE()`	SQL function	`REPLACE()`; identical syntax and implementation
`TRIM()`	SQL function	`TRIM()`; slightly different implementation
`TRUNC()`	SQL function	`TRUNCATE()`; slightly different syntax and implementation
`USE`	Switches to a new database instance; terminates the connection to the current database instance; all subsequent commands are referred to this database instance	`USE`; identical syntax, but does not terminate the connection to the current database
`USER`	SQL function	`USER()`; identical syntax, but slightly different implementation, and parentheses are mandatory in MySQL
`UTC_DIFF()`	SQL function	`UTC_DATE()`; provides a means to calculate the same result as `UTC_DIFF()`
`VALUE()`	SQL function, alias for `CO-ALESCE()`	`COALESCE()`; identical syntax and implementation
`VARIANCE()`	SQL function	`VARIANCE()`; added in MySQL 4.1.0
`WEEKOFYEAR()`	SQL function	`WEEKOFYEAR()`; added in MySQL 4.1.1

1.6. MySQL Development Roadmap

This section provides a snapshot of the MySQL development roadmap, including major features implemented in or planned for the various MySQL releases. The following sections provide information for each release series.

The current production release series is MySQL 4.1, which was declared stable for production use as of Version 4.1.7, released in October 2004. The previous production release series is MySQL 4.0, which was declared stable for production use as of Version 4.0.12, released in March 2003. Production status means that future 4.1 and 4.0 development is limited only to bugfixes. For the older MySQL 3.23 series, only critical bugfixes are made.

Active MySQL development currently is taking place in the MySQL 5.0 release series; this means that new features are being added there. MySQL 5.0 is available in beta status.

Before upgrading from one release series to the next, please see the notes at Section 2.10, "Upgrading MySQL".

The most requested features and the versions in which they were implemented or are scheduled for implementation are summarized in the following table:

Feature	MySQL Series
Foreign keys	3.23 (for the `InnoDB` storage engine)

Unions	4.0
Subqueries	4.1
R-trees	4.1 (for the `MyISAM` storage engine)
Stored procedures	5.0
Views	5.0
Cursors	5.0
Foreign keys	5.1 (implemented in 3.23 for `InnoDB`)
Triggers	5.0 and 5.1
Full outer joins	5.1
Constraints	5.1 (implemented in 3.23 for `InnoDB`)
Partitioning	5.1
Row-Based Replication	5.1

1.6.1. MySQL 4.0 in a Nutshell

MySQL Server 4.0 is available in production status.

MySQL 4.0 is available for download at http://dev.mysql.com/ and from our mirrors. MySQL 4.0 has been tested by a large number of users and is in production use at many large sites.

1.6.1.1. Features Available in MySQL 4.0

- Speed enhancements

    - MySQL 4.0 implemented a query cache that can give a major speed boost to applications with repetitive queries. See Section 5.12, "The MySQL Query Cache".

    - Version 4.0 further increased the speed of MySQL Server in a number of areas, such as bulk `INSERT` statements, searching on packed indexes, full-text searching (using `FULLTEXT` indexes), and `COUNT(DISTINCT)`.

- Introduction of Embedded MySQL Server

    - The Embedded Server library added in this release can easily be used to create standalone and embedded applications. The embedded server provides an alternative to using MySQL in a client/server environment. See Section 1.6.1.2, "The Embedded MySQL Server".

- `InnoDB` storage engine as standard

    - The `InnoDB` storage engine began to be offered as a standard feature of the MySQL server. This provided full support for ACID transactions, foreign keys with cascading `UPDATE` and `DELETE`, and row-level locking as standard features. See Chapter 15, *The `InnoDB` Storage Engine*.

- New functionality

    - The enhanced `FULLTEXT` search capabilities of MySQL Server 4.0 enabled `FULLTEXT` indexing of large text masses with both binary and natural-language searching logic. It became possible to customize minimal word length and define your own stop word lists in most human languages, enabling a broader class of applications to be built with MySQL Server. See Section 12.7, "Full-Text Search Functions".

- Standards compliance, portability, and migration

    - MySQL Server added support for the `UNION` statement, a standard SQL feature.

- Starting with version 4.0, MySQL runs natively on Novell NetWare 6.0 and higher. See Section 2.6, "Installing MySQL on NetWare".

- Features to simplify migration from other database systems to MySQL Server include TRUNCATE TABLE (as in Oracle) .

- Internationalization

- German-speaking users should note that MySQL 4.0 added support for a new character set, latin1_de, which ensures that words with umlauts are sorted in the same order as in German telephone books.

- **Usability enhancements**

- As of Version 4.0, most mysqld parameters (startup options) can be set without taking down the server. This is a convenient feature for database administrators. See Section 13.5.3, "SET Syntax".

- Multiple-table DELETE and UPDATE statements were added.

- On Windows, symbolic link handling at the database level was enabled by default. On Unix, the MyISAM storage engine added support for symbolic linking at the table level (and not just the database level as before).

- The addition of the SQL_CALC_FOUND_ROWS and FOUND_ROWS() functions made it possible to find out the number of rows a SELECT query that includes a LIMIT clause would have returned without that clause.

The news section of this manual includes a more in-depth list of MySQL 4.0 features. See Section E.3, "Changes in release 4.0.x (Production)".

1.6.1.2. The Embedded MySQL Server

The libmysqld embedded server library made MySQL Server suitable for a wider range of applications. Using this library, developers can embed MySQL Server into various applications and electronics devices, where the end user has no knowledge of there actually being an underlying database. Embedded MySQL Server is ideal for use in Internet appliances, public kiosks, turnkey hardware/software combination units, high performance Internet servers, self-contained databases distributed on CD-ROM, and so on.

The embedded MySQL library uses the same interface as the normal client library. See Section 23.1, "libmysqld, the Embedded MySQL Server Library". Embedded MySQL is available under the same dual-licensing model as the MySQL Server; see http://www.mysql.com/company/legal/licensing/ for more information.

On Windows there are two different libraries:

| libmysqld.lib | Dynamic library for threaded applications. |
| mysqldemb.lib | Static library for not threaded applications. |

1.6.2. MySQL 4.1 in a Nutshell

MySQL Server 4.0 laid the foundation for new features implemented in MySQL 4.1, such as subqueries and Unicode support, which were desired by many of our customers.

MySQL Server 4.1 is currently in production status, and binaries are available for download at http://dev.mysql.com/downloads/mysql/4.1.html. All binary releases pass our extensive test suite without any errors on the platforms on which we test. See Section E.2, "Changes in release 4.1.x (Production)".

For those wishing to use the most recent development source for MySQL 4.1, we also make our Bit-Keeper repositories publicly available. See Section 2.8.3, "Installing from the Development Source Tree".

1.6.2.1. Features Available in MySQL 4.1

This section lists features implemented in MySQL 4.1. Features that are available in MySQL 5.0 are described in Section D.1, "New Features in MySQL 5.0".

- **Support for subqueries and derived tables**:

    - A "subquery" is a `SELECT` statement nested within another statement. A "derived table" (an unnamed view) is a subquery in the `FROM` clause of another statement. See Section 13.2.8, "Subquery Syntax".

- **Speed enhancements**:

    - Faster binary client/server protocol with support for prepared statements and parameter binding. See Section 23.2.4, "C API Prepared Statements".

    - `BTREE` indexing is supported for `HEAP` tables, significantly improving response time for non-exact searches.

- **Added functionality**:

    - `CREATE TABLE` *tbl_name2* `LIKE` *tbl_name1* allows you to create, with a single statement, a new table with a structure exactly like that of an existing table.

    - The `MyISAM` storage engine added support for OpenGIS spatial types for storing geographical data. See Chapter 17, *Spatial Extensions in MySQL.*

    - Support was added for replication over SSL connections.

    - Support for a number of additional storage engines was implemented in the MySQL 4.1 release series:

        - The `EXAMPLE` storage engine is a "stub" engine that serves as an example in the MySQL source code for writing new storage engines, and is primarily of interest to developers. See Section 14.5, "The `EXAMPLE` Storage Engine".

        - `NDB Cluster` is the storage engine used by MySQL Cluster to implement tables that are partitioned over many computers. See Chapter 16, *MySQL Cluster.*

        - The `ARCHIVE` storage engine is used for storing large amounts of data without indexes in a very small footprint. See Section 14.7, "The `ARCHIVE` Storage Engine".

        - The `CSV` storage engine stores data in text files using comma-separated-values format. See Section 14.8, "The `CSV` Storage Engine".

        - The `BLACKHOLE` storage engine accepts but does not store data, and always returns an empty result set. It is for use primarily in replication. See Section 14.9, "The `BLACK-HOLE` Storage Engine".
        Note: These engines were implemented at different points in the development of MySQL 4.1. Please see the indicated sections for particulars in each case.

- **Standards compliance, portability, and migration**:

    - The enhanced client/server protocol available beginning with MySQL 4.1.1 provides the ability to pass multiple warnings to the client, rather than only a single result, making it much easier to track problems that occur in operations such as bulk data loading.

    - `SHOW WARNINGS` shows warnings for the last command. See Section 13.5.4.22, "`SHOW`

`WARNINGS` Syntax".

- **Internationalization and Localization**:

  - To support applications that require the use of local languages, the MySQL software added extensive Unicode support through the `utf8` and `ucs2` character sets.

  - Definition of character sets by column, table, and database. This allows for a high degree of flexibility in application design, particularly for multi-language Web sites. See Chapter 10, *Character Set Support*.

  - Per-connection time zones support, allowing individual clients to select their own time zones when necessary.

- **Usability enhancements**:

  - The addition of a server-based `HELP` command that can be used to get help information for SQL statements. This information is always applicable to the particular server version being used. Because this information is available by issuing an SQL statement, any client can access it. For example, the `help` command of the `mysql` command-line client has been modified to have this capability.

  - The improved client/server protocol allows multiple statements to be issued with a single call, and for returning multiple result sets. See Section 23.2.9, "C API Handling of Multiple Query Execution".

  - The syntax `INSERT ... ON DUPLICATE KEY UPDATE ...` was implemented. This allows you to update an existing row if the insert would have caused a duplicate value for a primary or unique index. See Section 13.2.4, "`INSERT` Syntax".

  - The aggregate function `GROUP_CONCAT()`, added the capability to concatenate column values from grouped rows into a single result string. See Section 12.10, "Functions and Modifiers for Use with `GROUP BY` Clauses".

The News section of this manual includes a more in-depth list of MySQL 4.1 features. See Section E.2, "Changes in release 4.1.x (Production)".

1.6.3. What's New in MySQL 5.0

The following features are implemented in MySQL 5.0.

- **`BIT` Data Type**: Can be used to store numbers in binary notation. See Section 11.1.1, "Overview of Numeric Types".

- **Cursors**: Elementary support for server-side cursors. See Section 18.2.11, "Cursors".

- **Data Dictionary (Information Schema)**: The introduction of the `INFORMATION_SCHEMA` database in MySQL 5.0 provided a standards-compliant means for accessing the MySQL Server's metadata, that is, data about the databases (schemas) on the server and the objects which they contain. See Chapter 21, *The `INFORMATION_SCHEMA` Information Database*.

- **Instance Manager**: Can be used to start and stop the MySQL Server, even from a remote host. See Section 5.2, "The MySQL Instance Manager".

- **Precision Math**: MySQL 5.0 introduced stricter criteria for acceptance or rejection of data, and implemented a new library for fixed-point arithmetic. These contributed to a much higher degree of accuracy for mathematical operations and greater control over invalid values. See Chapter 22, *Precision Math*.

- **Storage Engines**: Storage engines added in MySQL 5.0 include `ARCHIVE` and `FEDERATED`.

See Section 14.7, "The ARCHIVE Storage Engine" and Section 14.6, "The FEDERATED Storage Engine".

- **Stored Routines**: Support for named stored procedures and stored functions was implemented in MySQL 5.0. See Chapter 18, *Stored Procedures and Functions*.

- **Strict Mode and Standard Error Handling**: MySQL 5.0 added a strict mode where by it follows standard SQL in a number of ways in which it did not previously. Support for standard SQLSTATE error messages was also implemented. See Section 5.3.2, "The Server SQL Mode".

- **Triggers**: MySQL 5.0 added limited support for triggers. See Chapter 19, *Triggers* and Section 1.8.5.4, "Stored Procedures and Triggers".

- **VARCHAR Data Type**: The maximum effective length of a VARCHAR column was increased to 65,532 bytes, and stripping of trailing whitespace was eliminated. See Section 11.4, "String Types".

- **Views**: MySQL 5.0 added support for named, updateable views. See Chapter 20, *Views* and Section 1.8.5.6, "Views".

For more detailed information on changes in MySQL 5.0, see Section E.1, "Changes in release 5.0.x (Development)".

For those wishing to take a look at the bleeding edge of MySQL development, we make our Bit-Keeper repository for MySQL publicly available. See Section 2.8.3, "Installing from the Development Source Tree".

1.7. MySQL Information Sources

1.7.1. MySQL Mailing Lists

This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

1.7.1.1. The MySQL Mailing Lists

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit http://lists.mysql.com/. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large message per day.

Please *do not* send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from lists.mysql.com to your site are propagated to the local list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

If you wish to have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the List-ID: or Delivered-To: headers to identify list messages.

The MySQL mailing lists are as follows:

- announce

  This list is for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- `mysql`

  This is the main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- `bugs`

  This list is for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See Section 1.7.1.3, "How to Report Bugs or Problems".

- `internals`

  This list is for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- `mysqldoc`

  This list is for people who work on the MySQL documentation: people from MySQL AB, translators, and other community members.

- `benchmarks`

  This list is for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, filesystem, disk system, and so on.

- `packagers`

  This list is for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.

- `java`

  This list is for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers, including MySQL Connector/J.

- `win32`

  This list is for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- `myodbc`

  This list is for all topics concerning connecting to the MySQL server with ODBC.

- `gui-tools`

  This list is for all topics concerning MySQL GUI tools, including `MySQL Administrator` and the `MySQL Control Center` graphical client.

- `cluster`

  This list is for discussion of MySQL Cluster.

- `dotnet`

  This list is for discussion of the MySQL server and the .NET platform. Mostly related to the MySQL Connector/Net provider.

- `plusplus`

  This list is for all topics concerning programming with the C++ API for MySQL.

- `perl`

  This list is for all topics concerning the Perl support for MySQL with `DBD::mysql`.

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from MySQL AB. This puts you in direct contact with MySQL developers.

The following table shows some MySQL mailing lists in languages other than English. These lists are not operated by MySQL AB.

- `<mysql-france-subscribe@yahoogroups.com>`

  A French mailing list.

- `<list@tinc.net>`

  A Korean mailing list. Email `subscribe mysql your@email.address` to this list.

- `<mysql-de-request@lists.4t2.com>`

  A German mailing list. Email `subscribe mysql-de your@email.address` to this list. You can find information about this mailing list at http://www.4t2.com/mysql/.

- `<mysql-br-request@listas.linkway.com.br>`

  A Portuguese mailing list. Email `subscribe mysql-br your@email.address` to this list.

- `<mysql-alta@elistas.net>`

  A Spanish mailing list. Email `subscribe mysql your@email.address` to this list.

1.7.1.2. Asking Questions or Reporting Bugs

Before posting a bug report or question, please do the following:

- Start by searching the MySQL online manual at http://dev.mysql.com/doc/. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. The change history (http://dev.mysql.com/doc/mysql/en/News.html) can be particularly useful since it is quite possible that a newer version contains a solution to your problem.

- Search in the bugs database at http://bugs.mysql.com/ to see whether the bug has been reported and fixed.

- Search the MySQL mailing list archives at http://lists.mysql.com/.

- You can also use http://www.mysql.com/search/ to search all the Web pages (including the manual) that are located at the MySQL AB Web site.

If you can't find an answer in the manual or the archives, check with your local MySQL expert. If you still can't find an answer to your question, please follow the guidelines on sending mail to a MySQL mailing list, outlined in the next section, before contacting us.

1.7.1.3. How to Report Bugs or Problems

The normal place to report bugs is http://bugs.mysql.com/, which is the address for our bugs database. This database is public, and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you don't waste your time doing things that may not help us much or at all.

We encourage everyone to use the `mysqlbug` script to generate a bug report (or a report about any problem). `mysqlbug` can be found in the `scripts` directory (source distribution) and in the `bin` directory under your MySQL installation directory (binary distribution). If you are unable to use `mysqlbug` (for example, if you are running on Windows), it is still vital that you include all the necessary information noted in this section (most importantly, a description of the operating system and the MySQL version).

The `mysqlbug` script helps you generate a report by determining much of the following information automatically, but if something important is missing, please include it with your message. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test < script_file` on the included test case or by running the shell or Perl script that is included in the bug report.

All bugs posted in the bugs database at http://bugs.mysql.com/ are corrected or documented in the next MySQL release. If only minor code changes are needed to correct a problem, we may also post a patch that fixes the problem.

If you have found a sensitive security bug in MySQL, you can send email to `<security@mysql.com>`.

If you have a repeatable bug report, please report it to the bugs database at http://bugs.mysql.com/. Note that even in this case it's good to run the `mysqlbug` script first to find information about your system. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

To report other problems, you can use one of the MySQL mailing lists.

Remember that it is possible for us to respond to a message containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details don't matter. A good principle is this: If you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution used, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). This is highly relevant information, and in 99 cases out of 100, the bug report is useless without it. Very often we get questions like, "Why doesn't this work for me?" Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Sometimes the error is platform-dependent; in such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler, if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you use. Note that every compiling problem should be regarded as a bug and reported accordingly.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See Section F.1.6, "Making a Test Case If You Experience Table Corruption".

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives using programs, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) You should never try to reproduce from memory what the error message was; instead, copy and paste the entire message into your report.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See Section 24.1.1.9, "How to Report MyODBC Problems or Bugs".

Please remember that many of the people who read your report do so using an 80-column display. When generating reports or examples using the `mysql` command-line tool, you should therefore use the `--vertical` option (or the `\G` statement terminator) for output that would exceed the available width for such a display (for example, with the `EXPLAIN SELECT` statement; see the example later in this section).

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 4.0.12). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.

- The manufacturer and model of the machine on which you experience the problem.

- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the "Help/About Windows" menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.

- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.

- If you are using a source distribution of the MySQL software, the name and version number of the compiler used are needed. If you have a binary distribution, the distribution name is needed.

- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.

- If `mysqld` died, you should also report the query that crashed `mysqld`. You can usually find this out by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes See Section F.1.5, "Using Log Files to Find Cause of Errors in `mysqld`".

- If a database table is related to the problem, include the output from `mysqldump --no-data db_name tbl_name`. This is very easy to do and is a powerful way to get information about any table in a database. The information helps us create a situation matching the one you have experienced.

- For speed-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each involved table. The more information you give about your situation, the more likely it is that someone can help you.

  The following is an example of a very good bug report. It should be posted with the `mysqlbug` script. The example uses the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements whose output width would otherwise exceed that of an 80-column display device.

  ```
  mysql> SHOW VARIABLES;
  mysql> SHOW COLUMNS FROM ...\G
          <output from SHOW COLUMNS>
  mysql> EXPLAIN SELECT ...\G
          <output from EXPLAIN>
  mysql> FLUSH STATUS;
  ```

```
mysql> SELECT ...;
        <A short version of the output from SELECT,
        including the time taken to run the query>
mysql> SHOW STATUS;
        <output from SHOW STATUS>
```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should post it on http://bugs.mysql.com/ for high-priority treatment.

  If you can't provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your mail to provide some information on how your system is performing.

- If you can't produce a test case with only a few rows, or if the test table is too big to be mailed to the mailing list (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem.

  Create a compressed archive of your files using `tar` and `gzip` or `zip`, and use FTP to transfer the archive to ftp://ftp.mysql.com/pub/mysql/upload/. Then enter the problem into our bugs database at http://bugs.mysql.com/.

- If you think that the MySQL server produces a strange result from a query, include not only the result, but also your opinion of what the result should be, and an account describing the basis for your opinion.

- When giving an example of the problem, it's better to use the variable names, table names, and so on that exist in your actual situation than to come up with new names. The problem could be related to the name of a variable or table. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. In case you have data that you don't want to show to others, you can use FTP to transfer it to ftp://ftp.mysql.com/pub/mysql/upload/. If the information is really top secret and you don't want to show it even to us, then go ahead and provide an example using other names, but please regard this as the last choice.

- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often keys to answers and are very relevant. It is never a bad idea to include them. If you use any modules, such as Perl or PHP, please include the version numbers of those as well.

- If your question is related to the privilege system, please include the output of `mysqlaccess`, the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should first run `mysqlaccess`. After this, execute `mysqladmin reload version` and try to connect with the program that gives you trouble. `mysqlaccess` can be found in the `bin` directory under your MySQL installation directory.

- If you have a patch for a bug, do include it. But don't assume that the patch is all we need, or that we can use it, if you don't provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all; if so, we can't use it.

  If we can't verify exactly what the purpose of the patch is, we won't use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch won't work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team can't guess such things without first using a debugger to determine the real cause of a bug.

- Indicate in your bug report that you have checked the reference manual and mail archive so that

others know you have tried to solve the problem yourself.

- If you get a `parse error`, please check your syntax closely. If you can't find something wrong with it, it's extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual at http://dev.mysql.com/doc/ doesn't cover the syntax you are using, MySQL Server doesn't support your query. In this case, your only options are to implement the syntax yourself or email `<licensing@mysql.com>` and ask for an offer to implement it.

  If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server. See Appendix E, *MySQL Change History*.

- If your problem is that your data appears corrupt or you get errors when you access a particular table, you should first check and then try to repair your tables with `CHECK TABLE` and `RE-PAIR TABLE` or with `myisamchk`. See Chapter 5, *Database Administration*.

  If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` command.

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See Section 5.10.1, "The Error Log". Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it's much easier for us to provide you with a fix for the problem. See Section A.1, "How to Determine What Is Causing a Problem".

- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software are thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See Section 2.1.2, "Choosing Which MySQL Distribution to Install".

If you are a support customer, please cross-post the bug report to `<mysql-support@mysql.com>` for higher-priority treatment, as well as to the appropriate mailing list to see whether someone else has experienced (and perhaps solved) the problem.

For information on reporting bugs in MyODBC, see Section 24.1.1.9, "How to Report MyODBC Problems or Bugs".

For solutions to some common problems, see Appendix A, *Problems and Common Errors*.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

1.7.1.4. Guidelines for Answering Questions on the Mailing List

If you consider your answer to have broad interest, you may want to post it to the mailing list instead of replying directly to the individual who asked. Try to make your answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply; don't feel obliged to quote the entire original message.

Please don't post mail messages from your browser with HTML mode turned on. Many users don't read mail with a browser.

1.7.2. MySQL Community Support on IRC (Internet Relay Chat)

In addition to the various MySQL mailing lists, you can find experienced community people on IRC (Internet Relay Chat). These are the best networks/channels currently known to us:

- **freenode** (see http://www.freenode.net/ for servers)

  - #mysql Primarily MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl or C in combination with MySQL are also common.

If you are looking for IRC client software to connect to an IRC network, take a look at xChat (http://www.xchat.org/). X-Chat (GPL licensed) is available for Unix as well as for Windows platforms (a free Windows build of X-Chat is available at http://www.silverex.org/download/).

1.7.3. MySQL Community Support at the MySQL Forums

The latest community support resource are the forums at http://forums.mysql.com.

There are a variety of forums available, grouped in the following general categories:

- Migration

- MySQL Usage

- MySQL Connectors

- Programming Languages

- Tools

- 3rd-Party Applications

- Storage Engines

- MySQL Technology

- SQL Standards

- Business

1.8. MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, "SQL-92" refers to the standard released in 1992, "SQL:1999" refers to the standard released in 1999, and "SQL:2003" refers to the current version of the standard. We use the phrase "the SQL standard" to mean the current version of the SQL Standard at any time.

Our goal is to not restrict MySQL Server usability for any usage without a very good reason for doing so. Even if we don't have the resources to perform development for every possible use, we are always willing to help and offer suggestions to people who are trying to use MySQL Server in new

territories.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The HANDLER interface in MySQL Server 4.0 is an example of this strategy. See Section 13.2.3, "HANDLER Syntax".

We continue to support transactional and non-transactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium size databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-size databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

Currently, we are not targeting realtime support, although MySQL replication capabilities offer significant functionality.

Database cluster support exists through third-party clustering solutions as well as the integration of our acquired NDB Cluster technology, available from version 4.1.2. See Chapter 16, *MySQL Cluster*.

We are also looking at providing XML support in the database server.

1.8.1. What Standards MySQL Follows

We are aiming toward supporting the full ANSI/ISO SQL standard, but without making concessions to speed and quality of the code.

ODBC levels 0-3.51.

1.8.2. Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differentially for different clients. This allows an application to tailor server operation to its own requirements.

Modes define what SQL syntax MySQL should support and what kind of validation checks it should perform on the data. This makes it easier to use MySQL in a lot of different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting mysqld with the --sql-mode="modes" option. Beginning with MySQL 4.1, you can also change the mode after startup time by setting the sql_mode variable with a SET [SESSION|GLOBAL] sql_mode='modes' statement.

For more information on setting the server mode, see Section 5.3.2, "The Server SQL Mode".

1.8.3. Running MySQL in ANSI Mode

You can tell mysqld to use the ANSI mode with the --ansi startup option. See Section 5.3.1, "mysqld Command-Line Options".

Running the server in ANSI mode is the same as starting it with these options (specify the --sql_mode value on a single line):

```
--transaction-isolation=SERIALIZABLE
--sql-mode=REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,
IGNORE_SPACE
```

In MySQL 4.1, you can achieve the same effect with these two statements (specify the sql_mode

value on a single line):

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,
IGNORE_SPACE';
```

See Section 1.8.2, "Selecting SQL Modes".

In MySQL 4.1.1, the `sql_mode` options shown can be also be set with this statement:

```
SET GLOBAL sql_mode='ansi';
```

In this case, the value of the `sql_mode` variable is set to all options that are relevant for ANSI mode. You can check the result like this:

```
mysql> SET GLOBAL sql_mode='ansi';
mysql> SELECT @@global.sql_mode;
        -> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,
            IGNORE_SPACE,ANSI';
```

1.8.4. MySQL Extensions to Standard SQL

The MySQL Server includes some extensions that you probably won't find in other SQL DBMSs. Be warned that if you use them, your code won't be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the form `/*! ... */`. In this case, MySQL Server parses and execute the code within the comment as it would any other MySQL statement, but other SQL servers will ignore the extensions. For example:

```
SELECT /*! STRAIGHT_JOIN */ col_name FROM table1,table2 WHERE ...
```

If you add a version number after the '!' character, the syntax within the comment is executed only if the MySQL version is equal to or newer than the specified version number:

```
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

This means that if you have Version 3.23.02 or newer, MySQL Server uses the TEMPORARY keyword.

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

    MySQL Server maps each database to a directory under the MySQL data directory, and tables within a database to filenames in the database directory. This has a few implications:

    -
        Database names and table names are case sensitive in MySQL Server on operating systems that have case-sensitive filenames (such as most Unix systems). See Section 9.2.2, "Identifier Case Sensitivity".

    - You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the MyISAM or ISAM storage engines. For example, to rename a MyISAM table, rename the .MYD, .MYI, and .frm files to which the table corresponds.

    Database, table, index, column, or alias names may begin with a digit (but may not consist solely of digits).

- General language syntax

- Strings may be enclosed by either '"' or ''', not just by '''.

- Use of '\' as an escape character in strings.

- In SQL statements, you can access tables from different databases with the *db_name.tbl_name* syntax. Some SQL servers provide the same functionality but call this `User  space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table...IN my_tablespace`.

- SQL statement syntax

  - The `ANALYZE  TABLE`, `CHECK  TABLE`, `OPTIMIZE  TABLE`, and `REPAIR  TABLE` statements.

  - The `CREATE DATABASE` and `DROP  DATABASE` statements. See Section 13.1.3, "CRE-ATE DATABASE Syntax".

  - The `DO` statement.

  - `EXPLAIN  SELECT` to get a description of how tables are joined.

  - The `FLUSH` and `RESET` statements.

  - The `SET` statement. See Section 13.5.3, "`SET` Syntax".

  - The `SHOW` statement. See Section 13.5.4, "`SHOW` Syntax".

  - Use of `LOAD  DATA  INFILE`. In many cases, this syntax is compatible with Oracle's `LOAD DATA  INFILE`. See Section 13.2.5, "`LOAD  DATA  INFILE` Syntax".

  - Use of `RENAME  TABLE`. See Section 13.1.9, "`RENAME  TABLE` Syntax".

  - Use of `REPLACE` instead of `DELETE` + `INSERT`. See Section 13.2.6, "`REPLACE` Syntax".

  - Use of `CHANGE  col_name`, `DROP  col_name`, or `DROP  INDEX`, `IGNORE` or `RENAME` in an `ALTER  TABLE` statement. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER  TABLE` statement. See Section 13.1.2, "`ALTER  TABLE` Syntax".

  - Use of index names, indexes on a prefix of a field, and use of `INDEX` or `KEY` in a `CREATE TABLE` statement. See Section 13.1.5, "`CREATE  TABLE` Syntax".

  - Use of `TEMPORARY` or `IF  NOT  EXISTS` with `CREATE  TABLE`.

  - Use of `IF  EXISTS` with `DROP  TABLE`.

  - You can drop multiple tables with a single `DROP  TABLE` statement.

  - The `ORDER  BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.

  - `INSERT INTO ... SET col_name = ...` syntax.

  - The `DELAYED` clause of the `INSERT` and `REPLACE` statements.

  - The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.

  - Use of `INTO  OUTFILE` and `STRAIGHT_JOIN` in a `SELECT` statement. See Section 13.2.7, "`SELECT` Syntax".

  - The `SQL_SMALL_RESULT` option in a `SELECT` statement.

  - You don't need to name all selected columns in the `GROUP  BY` part. This gives better performance for some very specific, but quite normal queries. See Section 12.10, "Functions

and Modifiers for Use with `GROUP BY` Clauses".

- You can specify `ASC` and `DESC` with `GROUP BY`.

- The ability to set variables in a statement with the `:=` assignment operator:

```
mysql> SELECT @a:=SUM(total),@b=COUNT(*),@a/@b AS avg
    -> FROM test_table;
mysql> SELECT @t1:=(@t2:=1)+@t3:=4,@t1,@t2,@t3;
```

- Column types

  - The column types `MEDIUMINT`, `SET`, `ENUM`, and the different `BLOB` and `TEXT` types.

  - The column attributes `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL`.

- Functions and operators

  - To make it easier for users who come from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.

  - MySQL Server understands the `||` and `&&` operators to mean logical OR and AND, as in the C programming language. In MySQL Server, `||` and `OR` are synonyms, as are `&&` and `AND`. Because of this nice syntax, MySQL Server doesn't support the standard SQL `||` operator for string concatenation; use `CONCAT()` instead. Because `CONCAT()` takes any number of arguments, it's easy to convert use of the `||` operator to MySQL Server.

  - Use of `COUNT(DISTINCT list)` where `list` has more than one element.

  - All string comparisons are case-insensitive by default, with sort ordering determined by the current character set (cp1252 Latin1 by default). If you don't like this, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather then a lexical ordering.

  - The `%` operator is a synonym for `MOD()`. That is, `N % M` is equivalent to `MOD(N,M)`. `%` is supported for C programmers and for compatibility with PostgreSQL.

  - The `=, <>, <= ,<, >=,>, <<, >>, <=>`, `AND`, `OR`, or `LIKE` operators may be used in column comparisons to the left of the `FROM` in `SELECT` statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM tbl_name;
```

  - The `LAST_INSERT_ID()` function that returns the most recent `AUTO_INCREMENT` value. See Section 12.9.3, "Information Functions".

  - `LIKE` is allowed on numeric columns.

  - The `REGEXP` and `NOT REGEXP` extended regular expression operators.

  - `CONCAT()` or `CHAR()` with one argument or more than two arguments. (In MySQL Server, these functions can take any number of arguments.)

  - The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `PASSWORD()`, `ENCRYPT()`, `MD5()`, `ENCODE()`, `DECODE()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.

  - Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.

  - The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See Section 12.10, "Functions and Modifiers for Use with `GROUP BY`

Clauses”.

For a prioritized list indicating when new extensions are added to MySQL Server, you should consult the online MySQL TODO list at http://dev.mysql.com/doc/mysql/en/TODO.html. That is the latest version of the TODO list in this manual. See Appendix D, *MySQL and the Future (the TODO)*.

1.8.5. MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- For `VARCHAR` columns, trailing spaces are removed when the value is stored. (Fixed in MySQL 5.0.3). See Section A.8, “Known Issues in MySQL”.

- In some cases, `CHAR` columns are silently converted to `VARCHAR` columns when you define a table or alter its structure. (Fixed in MySQL 5.0.3). See Section 13.1.5.1, “Silent Column Specification Changes”.

- Privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. See Section 13.5.1.3, “`GRANT` and `REVOKE` Syntax”.

- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See Section 12.8, “Cast Functions and Operators”.

- Standard SQL requires that a `HAVING` clause in a `SELECT` statement be able to refer to columns in the `GROUP BY` clause. This cannot be done before MySQL 5.0.2.

1.8.5.1. Subqueries

MySQL 4.1 supports subqueries and derived tables. A “subquery” is a `SELECT` statement nested within another statement. A “derived table” (an unnamed view) is a subquery in the `FROM` clause of another statement. See Section 13.2.8, “Subquery Syntax”.

For MySQL versions older than 4.1, most subqueries can be rewritten using joins or other methods. See Section 13.2.8.11, “Rewriting Subqueries as Joins for Earlier MySQL Versions” for examples that show how to do this.

1.8.5.2. `SELECT INTO TABLE`

MySQL Server doesn't support the Sybase SQL extension: `SELECT ... INTO TABLE ....` Instead, MySQL Server supports the standard SQL syntax `INSERT INTO ... SELECT ...`, which is basically the same thing. See Section 13.2.4.1, “`INSERT ... SELECT` Syntax”.

```
INSERT INTO tbl_temp2 (fld_id)
    SELECT tbl_temp1.fld_order_id
    FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT INTO OUTFILE ...` or `CREATE TABLE ... SELECT`.

From version 5.0, MySQL supports `SELECT ... INTO` with user variables. The same syntax may also be used inside stored procedures using cursors and local variables. See Section 18.2.9.3, “`SELECT ... INTO` Statement”.

1.8.5.3. Transactions and Atomic Operations

MySQL Server (version 3.23-max and all versions 4.0 and above) supports transactions with the `InnoDB` and `BDB` transactional storage engines. `InnoDB` provides *full* `ACID` compliance. See Chapter 14, *MySQL Storage Engines and Table Types*.

The other non-transactional storage engines in MySQL Server (such as `MyISAM`) follow a different paradigm for data integrity called "atomic operations." In transactional terms, `MyISAM` tables effectively always operate in `AUTOCOMMIT=1` mode. Atomic operations often offer comparable integrity with higher performance.

With MySQL Server supporting both paradigms, you can decide whether your applications are best served by the speed of atomic operations or the use of transactional features. This choice can be made on a per-table basis.

As noted, the trade-off for transactional versus non-transactional table types lies mostly in performance. Transactional tables have significantly higher memory and diskspace requirements, and more CPU overhead. On the other hand, transactional table types such as `InnoDB` also offer many significant features. MySQL Server's modular design allows the concurrent use of different storage engines to suit different requirements and deliver optimum performance in all situations.

But how do you use the features of MySQL Server to maintain rigorous integrity even with the non-transactional `MyISAM` tables, and how do these features compare with the transactional table types?

1. If your applications are written in a way that is dependent on being able to call `ROLLBACK` rather than `COMMIT` in critical situations, transactions are more convenient. Transactions also ensure that unfinished updates or corrupting activities are not committed to the database; the server is given the opportunity to do an automatic rollback and your database is saved.

    If you use non-transactional tables, MySQL Server in almost all cases allows you to resolve potential problems by including simple checks before updates and by running simple scripts that check the databases for inconsistencies and automatically repair or warn if such an inconsistency occurs. Note that just by using the MySQL log or even adding one extra log, you can normally fix tables perfectly with no data integrity loss.

2. More often than not, critical transactional updates can be rewritten to be atomic. Generally speaking, all integrity problems that transactions solve can be done with `LOCK TABLES` or atomic updates, ensuring that there are no automatic aborts from the server, which is a common problem with transactional database systems.

3. To be safe with MySQL Server, whether or not using transactional tables, you only need to have backups and have binary logging turned on. With this you can recover from any situation that you could with any other transactional database system. It is always good to have backups, regardless of which database system you use.

The transactional paradigm has its benefits and its drawbacks. Many users and application developers depend on the ease with which they can code around problems where an abort appears to be, or is necessary. However, even if you are new to the atomic operations paradigm, or more familiar with transactions, do consider the speed benefit that non-transactional tables can offer on the order of three to five times the speed of the fastest and most optimally tuned transactional tables.

In situations where integrity is of highest importance, MySQL Server offers transaction-level reliability and integrity even for non-transactional tables. If you lock tables with `LOCK TABLES`, all updates stall until integrity checks are made. If you obtain a `READ LOCAL` lock (as opposed to a write lock) for a table that allows concurrent inserts at the end of the table, reads are allowed, as are inserts by other clients. The newly inserted records are not be seen by the client that has the read lock until it releases the lock. With `INSERT DELAYED`, you can queue inserts into a local queue, until the locks are released, without having the client wait for the insert to complete. See Section 13.2.4.2, "`INSERT DELAYED` Syntax".

"Atomic," in the sense that we mean it, is nothing magical. It only means that you can be sure that while each specific update is running, no other user can interfere with it, and there can never be an automatic rollback (which can happen with transactional tables if you are not very careful). MySQL

Server also guarantees that there are no dirty reads.

Following are some techniques for working with non-transactional tables:

- Loops that need transactions normally can be coded with the help of `LOCK TABLES`, and you don't need cursors to update records on the fly.

- To avoid using `ROLLBACK`, you can use the following strategy:

  1. Use `LOCK TABLES` to lock all the tables you want to access.

  2. Test the conditions that must be true before performing the update.

  3. Update if everything is okay.

  4. Use `UNLOCK TABLES` to release your locks.

  This is usually a much faster method than using transactions with possible rollbacks, although not always. The only situation this solution doesn't handle is when someone kills the threads in the middle of an update. In this case, all locks are released but some of the updates may not have been executed.

- You can also use functions to update records in a single operation. You can get a very efficient application by using the following techniques:

  - Modify columns relative to their current value.

  - Update only those columns that actually have changed.

  For example, when we are doing updates to some customer information, we update only the customer data that has changed and test only that none of the changed data, or data that depends on the changed data, has changed compared to the original row. The test for changed data is done with the `WHERE` clause in the `UPDATE` statement. If the record wasn't updated, we give the client a message: "Some of the data you have changed has been changed by another user." Then we show the old row versus the new row in a window so that the user can decide which version of the customer record to use.

  This gives us something that is similar to column locking but is actually even better because we only update some of the columns, using values that are relative to their current values. This means that typical `UPDATE` statements look something like these:

  ```
  UPDATE tablename SET pay_back=pay_back+125;

  UPDATE customer
    SET
      customer_date='current_date',
      address='new address',
      phone='new phone',
      money_owed_to_us=money_owed_to_us-125
    WHERE
      customer_id=id AND address='old address' AND phone='old phone';
  ```

  This is very efficient and works even if another client has changed the values in the `pay_back` or `money_owed_to_us` columns.

-

  In many cases, users have wanted `LOCK TABLES` and/or `ROLLBACK` for the purpose of managing unique identifiers. This can be handled much more efficiently without locking or rolling back by using an `AUTO_INCREMENT` column and either the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.9.3, "Information Functions". See Section 23.2.3.34, "`mysql_insert_id()`".

  You can generally code around the need for row-level locking. Some situations really do need it,

and `InnoDB` tables support row-level locking. With `MyISAM` tables, you can use a flag column in the table and do something like the following:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID;
```

MySQL returns `1` for the number of affected rows if the row was found and `row_flag` wasn't `1` in the original row.

You can think of it as though MySQL Server changed the preceding query to:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID AND row_flag <> 1;
```

1.8.5.4. Stored Procedures and Triggers

Stored procedures are implemented in MySQL version 5.0. See Chapter 18, *Stored Procedures and Functions*.

Basic triggers functionality is implemented in MySQL beginning with version 5.0.2, with further development planned in MySQL 5.1. See Chapter 19, *Triggers*.

1.8.5.5. Foreign Keys

In MySQL Server 3.23.44 and up, the `InnoDB` storage engine supports checking of foreign key constraints, including `CASCADE`, `ON DELETE`, and `ON UPDATE`. See Section 15.7.4, "FOREIGN KEY Constraints".

For storage engines other than `InnoDB`, MySQL Server parses the `FOREIGN KEY` syntax in `CREATE TABLE` statements, but does not use or store it. In the future, the implementation will be extended to store this information in the table specification file so that it may be retrieved by `mysqldump` and ODBC. At a later stage, foreign key constraints will be implemented for `MyISAM` tables as well.

Foreign key enforcement offers several benefits to database developers:

• Assuming proper design of the relationships, foreign key constraints make it more difficult for a programmer to introduce an inconsistency into the database.

• Centralized checking of constraints by the database server makes it unnecessary to perform these checks on the application side. This eliminates the possibility that different applications may not all check the constraints in the same way.

• Using cascading updates and deletes can simplify the application code.

• Properly designed foreign key rules aid in documenting relationships between tables.

Do keep in mind that these benefits come at the cost of additional overhead for the database server to perform the necessary checks. Additional checking by the server affects performance, which for some applications may be sufficiently undesirable as to be avoided if possible. (Some major commercial applications have coded the foreign-key logic at the application level for this reason.)

MySQL gives database developers the choice of which approach to use. If you don't need foreign keys and want to avoid the overhead associated with enforcing referential integrity, you can choose another table type instead, such as `MyISAM`. (For example, the `MyISAM` storage engine offers very fast performance for applications that perform only `INSERT` and `SELECT` operations, because the inserts can be performed concurrently with retrievals. See Section 7.3.2, "Table Locking Issues".)

If you choose not to take advantage of referential integrity checks, keep the following considerations

in mind:

- In the absence of server-side foreign key relationship checking, the application itself must handle relationship issues. For example, it must take care to insert rows into tables in the proper order, and to avoid creating orphaned child records. It must also be able to recover from errors that occur in the middle of multiple-record insert operations.

- If `ON DELETE` is the only referential integrity capability an application needs, note that as of MySQL Server 4.0, you can use multiple-table `DELETE` statements to delete rows from many tables with a single statement. See Section 13.2.1, "`DELETE` Syntax".

- A workaround for the lack of `ON DELETE` is to add the appropriate `DELETE` statement to your application when you delete records from a table that has a foreign key. In practice, this is often as quick as using foreign keys, and is more portable.

Be aware that the use of foreign keys can in some instances lead to problems:

- Foreign key support addresses many referential integrity issues, but it is still necessary to design key relationships carefully to avoid circular rules or incorrect combinations of cascading deletes.

- It is not uncommon for a DBA to create a topology of relationships that makes it difficult to restore individual tables from a backup. (MySQL alleviates this difficulty by allowing you to temporarily disable foreign key checks when reloading a table that depends on other tables. See Section 15.7.4, "`FOREIGN KEY` Constraints". As of MySQL 4.1.1, `mysqldump` generates dump files that take advantage of this capability automatically when reloaded.)

Note that foreign keys in SQL are used to check and enforce referential integrity, not to join tables. If you want to get results from multiple tables from a `SELECT` statement, you do this by performing a join between them:

```
SELECT * FROM t1, t2 WHERE t1.id = t2.id;
```

See Section 13.2.7.1, "`JOIN` Syntax". See Section 3.6.6, "Using Foreign Keys".

The `FOREIGN KEY` syntax without `ON DELETE ...` is often used by ODBC applications to produce automatic `WHERE` clauses.

1.8.5.6. Views

Views (including updatable views) are implemented in the 5.0 version of MySQL Server. Views are available in binary releases from 5.0.1 and up. See Chapter 20, *Views*.

Views are useful for allowing users to access a set of relations (tables) as if it were a single table, and limiting their access to just that. Views can also be used to restrict access to rows (a subset of a particular table). For access control to columns, you can also use the sophisticated privilege system in MySQL Server. See Section 5.6, "The MySQL Access Privilege System".

In designing an implementation of views, our ambitious goal, as much as is possible within the confines of SQL, has been full compliance with "Codd's Rule #6" for relational database systems: "All views that are theoretically updatable, should in practice also be updatable."

1.8.5.7. '--' as the Start of a Comment

Some other SQL databases use '--' to start comments. MySQL Server uses '#' as the start comment character. You can also use the C comment style `/* this is a comment */` with MySQL Server. See Section 9.5, "Comment Syntax".

MySQL Server 3.23.3 and above support the '--' comment style, provided the comment is fol-

lowed by a space (or by a control character such as a newline). The requirement for a space is to prevent problems with automatically generated SQL queries that have used something like the following code, where we automatically insert the value of the payment for `!payment!`:

```
UPDATE account SET credit=credit-!payment!
```

Think about what happens if the value of `payment` is a negative value such as `-1`:

```
UPDATE account SET credit=credit--1
```

`credit--1` is a legal expression in SQL, but if `--` is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all! This illustrates that allowing comments to start with '`--`' can have serious consequences.

Using our implementation of this method of commenting in MySQL Server 3.23.3 and up, `credit--1` is actually safe.

Another safe feature is that the `mysql` command-line client removes all lines that start with '`--`'.

The following information is relevant only if you are running a MySQL version earlier than 3.23.3:

If you have an SQL program in a text file that contains '`--`' comments, you should use the `replace` utility as follows to convert the comments to use '`#`' characters:

```
shell> replace " --" " #" < text-file-with-funny-comments.sql \
          | mysql db_name
```

instead of the usual:

```
shell> mysql db_name < text-file-with-funny-comments.sql
```

You can also edit the command file "in place" to change the '`--`' comments to '`#`' comments:

```
shell> replace " --" " #" -- text-file-with-funny-comments.sql
```

Change them back with this command:

```
shell> replace " #" " --" -- text-file-with-funny-comments.sql
```

1.8.6. How MySQL Deals with Constraints

MySQL allows you to work both with transactional tables that allow rollback and with non-transactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a non-transactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all. See Section D.3, "New Features Planned for the Near Future".

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course.

This means, for example, that the server may coerce illegal values to the closest legal values.

Beginning with MySQL 5.0.2, several SQL mode options are available to provide greater control over how accepting to be of bad data values and whether to continue executing a statement or abort it when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set at runtime, which enables individual clients to select the behavior most appropriate for their requirements. See Section 5.3.2, "The Server SQL Mode".

The following sections describe what happens for the different types of constraints.

1.8.6.1. `PRIMARY KEY` and `UNIQUE` Index Constraints

Normally, an error occurs when you try to `INSERT` or `UPDATE` a row that causes a primary key, unique key, or foreign key violation. If you are using a transactional storage engine such as `InnoDB`, MySQL automatically rolls back the statement. If you are using a non-transactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

If you wish to ignore such key violations, MySQL supports an `IGNORE` keyword for `INSERT` and `UPDATE`. In this case, MySQL ignores any key violations and continues processing with the next row. See Section 13.2.4, "`INSERT` Syntax". See Section 13.2.10, "`UPDATE` Syntax".

You can get information about the number of rows actually inserted or updated with the `mysql_info()` C API function. See Section 23.2.3.32, "`mysql_info()`". In MySQL 4.1 and up, you also can use the `SHOW WARNINGS` statement. See Section 13.5.4.22, "`SHOW WARNINGS` Syntax".

For the moment, only `InnoDB` tables support foreign keys. See Section 15.7.4, "`FOREIGN KEY` Constraints". Foreign key support in `MyISAM` tables is scheduled for implementation in MySQL 5.1.

1.8.6.2. Constraints on Invalid Data

Before MySQL 5.0.2, MySQL is forgiving of illegal or improper data values and coerces them to legal values for data entry. In MySQL 5.0.2 and up, that remains the default behavior, but you can select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. This section describes the default (forgiving) behavior of MySQL, as well as the newer strict SQL mode and how it differs.

The following holds true when you are not using strict mode. If you insert an "incorrect" value into a column, such as a `NULL` into a `NOT NULL` column or a too-large numeric value into a numeric column, MySQL sets the column to the "best possible value" instead of producing an error:

• If you try to store an out of range value in a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value in the column.

• For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.

• If you try to store a string that doesn't start with a number into a numeric column, MySQL Server stores 0.

• MySQL allows you to store certain incorrect date values into `DATE` and `DATETIME` columns (such as `'2000-02-31'` or `'2000-02-00'`). The idea is that it's not the job of the SQL server to validate dates. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special date value `'0000-00-00'` is stored in the column instead.

• If you try to store `NULL` into a column that doesn't take `NULL` values, an error occurs for single-row `INSERT` statements. For multiple-row `INSERT` statements or for `INSERT INTO ...`

SELECT statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string (`' '`) for string types, and the "zero" value for date and time types. Implicit default values are discussed in Section 13.1.5, "`CREATE TABLE` Syntax".

- If an `INSERT` statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit `DEFAULT` clause. If the definition has no such `DEFAULT` clause, MySQL inserts the implicit default value for the column data type.

The reason for the preceding rules is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be "half done," which is probably the worst possible scenario. In this case, it's better to "do the best you can" and then continue as if nothing happened.

In MySQL 5.0.2 and up, you can select stricter treatment of input values by using the `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` SQL modes. See Section 5.3.2, "The Server SQL Mode".

`STRICT_TRANS_TABLES` works like this:

- For transactional storage engines, bad data values occurring anywhere in the statement cause the statement to abort and roll back.

- For non-transactional storage engines, the statement aborts if the error occurs in the first row to be inserted or updated. (In this case, the statement can be regarded to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with `STRICT_TRANS_TABLES`, a wrong value causes MySQL to roll back, if it can, all updates done so far.

For stricter checking, enable `STRICT_ALL_TABLES`. This is the same as `STRICT_TRANS_TABLES` except that for non-transactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a non-transactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for non-transactional tables, either use single-row statements or else use `STRICT_TRANS_TABLES` if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only legal values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

1.8.6.3. `ENUM` and `SET` Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. However, before MySQL 5.0.2, `ENUM` and `SET` are not real constraints. This is for the same reasons that `NOT NULL` is not honored. See Section 1.8.6.2, "Constraints on Invalid Data".

`ENUM` columns always have a default value. If you don't specify a default value, then it is `NULL` for columns that can have `NULL`, otherwise the first enumeration value is used as the default value.

If you insert an incorrect value into an `ENUM` column or if you force a value into an `ENUM` column with `IGNORE`, it is set to the reserved enumeration value of 0, which is displayed as an empty string in string context. See Section 11.4.4, "The `ENUM` Type".

If you insert an incorrect value into a `SET` column, the incorrect value is ignored. For example, if the column can contain the values `'a'`, `'b'`, and `'c'`, an attempt to assign `'a,x,b,y'` results in a value of `'a,b'`. See Section 11.4.5, "The `SET` Type".

As of MySQL 5.0.2, you can configure the server to use strict SQL mode. See Section 5.3.2, "The Server SQL Mode". When strict mode is enabled, the definition of a ENUM or SET column does act as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An ENUM value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as ENUM('a','b','c'), values such as '', 'd', and 'ax' are illegal and are rejected.

- A SET value must be the empty string or a value consisting of one or more of the values listed in the column definition separated by commas. For a column defined as SET('a','b','c'), values such as 'd', and 'a,b,c,d' are illegal and are rejected.

Errors for invalid values can be suppressed in strict mode if you use INSERT IGNORE or UPDATE IGNORE. In this case, a warning is generated rather than an error. For ENUM, the value is inserted as the error member (0). For SET, the value is inserted as given except that any invalid substrings are deleted. For example, 'a,x,b,y' results in a value of 'a,b', as described earlier.

Chapter 2. Installing MySQL

This chapter describes how to obtain and install MySQL:

1. **Determine whether your platform is supported.** Please note that not all supported systems are equally good for running MySQL on them. On some it is much more robust and efficient than others. See Section 2.1.1, "Operating Systems Supported by MySQL" for details.

2. **Choose which distribution to install.** Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. We also provide public access to our current source tree for those who want to see our most recent developments and help us test new code. To determine which version and type of distribution you should use, see Section 2.1.2, "Choosing Which MySQL Distribution to Install".

3. **Download the distribution that you want to install.** For a list of sites from which you can obtain MySQL, see Section 2.1.3, "How to Get MySQL". You can verify the integrity of the distribution using the instructions in Section 2.1.4, "Verifying Package Integrity Using MD5 Checksums or `GnuPG`".

4. **Install the distribution.** To install MySQL from a binary distribution, use the instructions in Section 2.2, "Standard MySQL Installation Using a Binary Distribution". To install MySQL from a source distribution or from the current development source tree, use the instructions in Section 2.8, "MySQL Installation Using a Source Distribution".

   Note: If you plan to upgrade an existing version of MySQL to a newer version rather than installing MySQL for the first time, see Section 2.10, "Upgrading MySQL" for information about upgrade procedures and about issues that you should consider before upgrading.

   If you encounter installation difficulties, see Section 2.12, "Operating System-Specific Notes" for information on solving problems for particular platforms.

5. **Perform any necessary post-installation setup.** After installing MySQL, read Section 2.9, "Post-Installation Setup and Testing". This section contains important information about making sure the MySQL server is working properly. It also describes how to secure the initial MySQL user accounts, *which have no passwords* until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See Section 2.13, "Perl Installation Notes".

2.1. General Installation Issues

Before installing MySQL, you should do the following:

1. Determine whether or not MySQL runs on your platform.

2. Choose a distribution to install.

3. Download the distribution and verify its integrity.

This section contains the information necessary to carry out these steps. After doing so, you can use the instructions in later sections of the chapter to install the distribution that you choose.

2.1.1. Operating Systems Supported by MySQL

This section lists the operating systems on which you can expect to be able to run MySQL.

We use GNU Autoconf, so it is possible to port MySQL to all modern systems that have a C++ compiler and a working implementation of POSIX threads. (Thread support is needed for the server. To compile only the client code, the only requirement is a C++ compiler.) We use and develop the software ourselves primarily on Linux (SuSE and Red Hat), FreeBSD, and Sun Solaris (Versions 8 and 9).

MySQL has been reported to compile successfully on the following combinations of operating system and thread package. Note that for many operating systems, native thread support works only in the latest versions.

- AIX 4.x, 5.x with native threads. See Section 2.12.5.3, "IBM-AIX notes".

- Amiga.

- BSDI 2.x with the MIT-pthreads package. See Section 2.12.4.5, "BSD/OS Version 2.x Notes".

- BSDI 3.0, 3.1 and 4.x with native threads. See Section 2.12.4.5, "BSD/OS Version 2.x Notes".

- Digital Unix 4.x with native threads. See Section 2.12.5.5, "Alpha-DEC-UNIX Notes (Tru64)".

- FreeBSD 2.x with the MIT-pthreads package. See Section 2.12.4.1, "FreeBSD Notes".

- FreeBSD 3.x and 4.x with native threads. See Section 2.12.4.1, "FreeBSD Notes".

- FreeBSD 4.x with LinuxThreads. See Section 2.12.4.1, "FreeBSD Notes".

- HP-UX 10.20 with the DCE threads or the MIT-pthreads package. See Section 2.12.5.1, "HP-UX Version 10.20 Notes".

- HP-UX 11.x with the native threads. See Section 2.12.5.2, "HP-UX Version 11.x Notes".

- Linux 2.0+ with LinuxThreads 0.7.1+ or `glibc` 2.0.7+ for various CPU architectures. See Section 2.12.1, "Linux Notes".

- Mac OS X. See Section 2.12.2, "Mac OS X Notes".

- NetBSD 1.3/1.4 Intel and NetBSD 1.3 Alpha (requires GNU make). See Section 2.12.4.2, "NetBSD Notes".

- Novell NetWare 6.0. See Section 2.6, "Installing MySQL on NetWare".

- OpenBSD > 2.5 with native threads. OpenBSD < 2.5 with the MIT-pthreads package. See Section 2.12.4.3, "OpenBSD 2.5 Notes".

- OS/2 Warp 3, FixPack 29 and OS/2 Warp 4, FixPack 4. See Section 2.12.6, "OS/2 Notes".

- SCO OpenServer 5.0.X with a recent port of the FSU Pthreads package. See Section 2.12.5.8, "SCO UNIX and OpenServer 5.0.x Notes".

- SCO UnixWare 7.1.x. See Section 2.12.5.9, "SCO UnixWare 7.1.x and OpenUNIX 8.0.0 Notes".

- SCO Openserver 6.0.x. See Section 2.12.5.10, "SCO OpenServer 6.0.x Notes".

- SGI Irix 6.x with native threads. See Section 2.12.5.7, "SGI Irix Notes".

- Solaris 2.5 and above with native threads on SPARC and x86. See Section 2.12.3, "Solaris Notes".

- SunOS 4.x with the MIT-pthreads package. See Section 2.12.3, "Solaris Notes".

- Tru64 Unix. See Section 2.12.5.5, "Alpha-DEC-UNIX Notes (Tru64)".

- Windows 9x, Me, NT, 2000, XP, and 2003. See Section 2.3, "Installing MySQL on Windows".

Not all platforms are equally well-suited for running MySQL. How well a certain platform is suited for a high-load mission-critical MySQL server is determined by the following factors:

- General stability of the thread library. A platform may have an excellent reputation otherwise, but MySQL is only as stable as the thread library it calls, even if everything else is perfect.

- The capability of the kernel and the thread library to take advantage of symmetric multi-processor (SMP) systems. In other words, when a process creates a thread, it should be possible for that thread to run on a different CPU than the original process.

- The capability of the kernel and the thread library to run many threads that acquire and release a mutex over a short critical region frequently without excessive context switches. If the implementation of `pthread_mutex_lock()` is too anxious to yield CPU time, this hurts MySQL tremendously. If this issue is not taken care of, adding extra CPUs actually makes MySQL slower.

- General filesystem stability and performance.

- If your tables are big, the ability of the filesystem to deal with large files at all and to deal with them efficiently.

- Our level of expertise here at MySQL AB with the platform. If we know a platform well, we enable platform-specific optimizations and fixes at compile time. We can also provide advice on configuring your system optimally for MySQL.

- The amount of testing we have done internally for similar configurations.

- The number of users that have successfully run MySQL on the platform in similar configurations. If this number is high, the chances of encountering platform-specific surprises are much smaller.

Based on the preceding criteria, the best platforms for running MySQL at this point are x86 with SuSE Linux using a 2.4 kernel, and ReiserFS (or any similar Linux distribution) and SPARC with Solaris (2.7-9). FreeBSD comes third, but we really hope it joins the top club once the thread library is improved. We also hope that at some point we is able to include into the top category all other platforms on which MySQL currently compiles and runs okay, but not quite with the same level of stability and performance. This requires some effort on our part in cooperation with the developers of the operating system and library components that MySQL depends on. If you are interested in improving one of those components, are in a position to influence its development, and need more detailed instructions on what MySQL needs to run better, send an email message to the MySQL `internals` mailing list. See Section 1.7.1.1, "The MySQL Mailing Lists".

Please note that the purpose of the preceding comparison is not to say that one operating system is better or worse than another in general. We are talking only about choosing an OS for the specific purpose of running MySQL. With this in mind, the result of this comparison would be different if we considered more factors. In some cases, the reason one OS is better than the other could simply be that we have been able to put more effort into testing and optimizing for a particular platform. We are just stating our observations to help you decide which platform to use for running MySQL.

2.1.2. Choosing Which MySQL Distribution to Install

When preparing to install MySQL, you should decide which version to use. MySQL development occurs in several release series, and you can pick the one that best fits your needs. After deciding which version to install, you can choose a distribution format. Releases are available in binary or source format.

2.1.2.1. Choosing Which Version of MySQL to Install

The first decision to make is whether you want to use a production (stable) release or a development release. In the MySQL development process, multiple release series co-exist, each at a different stage of maturity:

- MySQL 5.0 is the newest development release series and is under very active development for new features. Alpha releases have been issued to allow more widespread testing.

- MySQL 4.1 is the current stable (production-quality) release series. New releases are issued for bugfixes. No new features are added that could diminish the code stability.

- MySQL 4.0 is the previous stable (production-quality) release series. New releases are issued for bugfixes. No new features are added that could diminish the code stability.

- MySQL 3.23 is the old stable (production-quality) release series. This series is retired, so new releases are issued only to fix critical bugs.

We don't believe in a complete freeze, as this also leaves out bugfixes and things that "must be done." "Somewhat frozen" means that we may add small things that "almost surely do not affect anything that's currently working." Naturally, relevant bugfixes from an earlier series propagate to later series.

Normally, if you are beginning to use MySQL for the first time or trying to port it to some system for which there is no binary distribution, we recommend going with the production release series. Currently this is MySQL 4.1. All MySQL releases, even those from development series, are checked with the MySQL benchmarks and an extensive test suite before being issued.

If you are running an old system and want to upgrade, but don't want to take the chance of having a non-seamless upgrade, you should upgrade to the latest version in the same release series you are using (where only the last part of the version number is newer than yours). We have tried to fix only fatal bugs and make small, relatively safe changes to that version.

If you want to use new features not present in the production release series, you can use a version from a development series. Note that development releases are not as stable as production releases.

If you want to use the very latest sources containing all current patches and bugfixes, you can use one of our BitKeeper repositories. These are not "releases" as such, but are available as previews of the code on which future releases are based.

The MySQL naming scheme uses release names that consist of three numbers and a suffix; for example, `mysql-4.1.2-alpha`. The numbers within the release name are interpreted like this:

- The first number (`4`) is the major version and also describes the file format. All Version 4 releases have the same file format.

- The second number (`1`) is the release level. Taken together, the major version and release level constitute the release series number.

- The third number (`2`) is the version number within the release series. This is incremented for each new release. Usually you want the latest version for the series you have chosen.

For each minor update, the last number in the version string is incremented. When there are major new features or minor incompatibilities with previous versions, the second number in the version string is incremented. When the file format changes, the first number is increased.

Release names also include a suffix to indicates the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- `alpha` indicates that the release contains some large section of new code that hasn't been 100% tested. Known bugs (usually there are none) should be documented in the News section. See Appendix E, *MySQL Change History*. There are also new commands and extensions in most alpha releases. Active development that may involve major code changes can occur in an alpha release, but everything is tested before issuing a release. For this reason, there should be no known bugs in any MySQL release.

- `beta` means that we are feature complete and that all new code has been tested. No major new features that could cause corruption in old code are added. There should be no known critical bugs. A version changes from alpha to beta when there haven't been any reported fatal bugs within an alpha version for at least a month and we have no plans to add any features that could make any old command unreliable.

  All API's, extern visible structures and columns for SQL commands will not change during future beta, release candidate, or production releases.

- `rc` is a release candidate; that is, a beta that has been around a while and seems to work fine. Only minor fixes are added. (A release candidate is what formerly was known as a gamma release.)

- If there is no suffix, it means that the version has been run for a while at many different sites with no reports of critical repeatable bugs other than platform-specific bugs. Only critical bugfixes are applied to the release. This is what we call a production (stable) or `General Availability' (GA) release.

MySQL uses a naming scheme that is slightly different from most other products. In general, it's relatively safe to use any version that has been out for a couple of weeks without being replaced with a new version within the release series.

All releases of MySQL are run through our standard tests and benchmarks to ensure that they are relatively safe to use. Because the standard tests are extended over time to check for all previously found bugs, the test suite keeps getting better.

All releases have been tested at least with:

- An internal test suite

  The `mysql-test` directory contains an extensive set of test cases. We run these tests for virtually every server binary. See Section 25.1.2, "MySQL Test Suite" for more information about this test suite.

- The MySQL benchmark suite

  This suite runs a range of common queries. It is also a test to see whether the latest batch of optimizations actually made the code faster. See Section 7.1.4, "The MySQL Benchmark Suite".

- The `crash-me` test

  This test tries to determine what features the database supports and what its capabilities and limitations are. See Section 7.1.4, "The MySQL Benchmark Suite".

Another test is that we use the newest MySQL version in our internal production environment, on at least one machine. We have more than 100GB of data to work with.

2.1.2.2. Choosing a Distribution Format

After choosing which version of MySQL to install, you should decide whether to use a binary distribution or a source distribution. In most cases, you should probably use a binary distribution, if one exists for your platform. Binary distributions are available in native format for many platforms, such as RPM files for Linux or DMG package installers for Mac OS X. Distributions also are available as

Zip archives or compressed `tar` files.

Reasons to choose a binary distribution include the following:

- Binary distributions generally are easier to install than source distributions.

- To satisfy different user requirements, we provide two different binary versions: one compiled with the non-transactional storage engines (a small, fast binary), and one configured with the most important extended options like transaction-safe tables. Both versions are compiled from the same source distribution. All native MySQL clients can connect to servers from either MySQL version.

  The extended MySQL binary distribution is marked with the `-max` suffix and is configured with the same options as `mysqld-max`. See Section 5.1.2, "The `mysqld-max` Extended MySQL Server".

  If you want to use the `MySQL-Max` RPM, you must first install the standard `MySQL-server` RPM.

Under some circumstances, you may be better off installing MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are "ready to run" at any place, but you may want to have even more flexibility to place MySQL components where you want.

- You want to configure `mysqld` with some extra features that are not included in the standard binary distributions. Here is a list of the most common extra options that you may want to use:

  - `--with-innodb` (default for MySQL 4.0 and up)

  - `--with-berkeley-db` (not available on all platforms)

  - `--with-raid`

  - `--with-libwrap`

  - `--with-named-z-libs` (this is done for some of the binaries)

  - `--with-debug[=full]`

- You want to configure `mysqld` without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.

- You have a special compiler (such as `pgcc`) or want to use compiler options that are better optimized for your processor. Binary distributions are compiled with options that should work on a variety of processors from the same processor family.

- You want to use the latest sources from one of the BitKeeper repositories to have access to all current bugfixes. For example, if you have found a bug and reported it to the MySQL development team, the bugfix is committed to the source repository and you can access it there. The bugfix does not appear in a release until a release actually is issued.

- You want to read (or modify) the C and C++ code that makes up MySQL. For this purpose, you should get a source distribution, because the source code is always the ultimate manual.

- Source distributions contain more tests and examples than binary distributions.

2.1.2.3. How and When Updates Are Released

MySQL is evolving quite rapidly here at MySQL AB and we want to share new developments with other MySQL users. We try to make a release when we have very useful features that others seem to have a need for.

We also try to help out users who request features that are easy to implement. We take note of what our licensed users want to have, and we especially take note of what our support customers want and try to help them out.

No one has to download a new release. The News section tells you if the new release has something you really want. See Appendix E, *MySQL Change History*.

We use the following policy when updating MySQL:

• Releases are issued within each series. For each release, the last number in the version is one more than the previous release within the same series.

• Production (stable) releases are meant to appear about 1-2 times a year. However, if small bugs are found, a release with only bugfixes is issued.

• Working releases/bugfixes to old releases are meant to appear about every 4-8 weeks.

• Binary distributions for some platforms are made by us for major releases. Other people may make binary distributions for other systems, but probably less frequently.

• We make fixes available as soon as we have identified and corrected small or non-critical but annoying bugs. The fixes are available immediately from our public BitKeeper repositories, and will be included in the next release.

• If by any chance a fatal bug is found in a release, we make a new release as soon as possible. (We would like other companies to do this, too!)

2.1.2.4. Release Philosophy—No Known Bugs in Releases

We put a lot of time and effort into making our releases bug-free. To our knowledge, we have not knowingly released a single MySQL version with any *known* "fatal" repeatable bugs. (A "fatal" bug is something that crashes MySQL under normal usage, produces incorrect answers for normal queries, or has a security problem.)

We have documented all open problems, bugs, and issues that are dependent on design decisions. See Section A.8, "Known Issues in MySQL".

Our aim is to fix everything that is fixable without risk of making a stable MySQL version less stable. In certain cases, this means we can fix an issue in the development versions, but not in the stable (production) version. Naturally, we document such issues so that users are aware of them.

Here is a description of how our build process works:

• We monitor bugs from our customer support list, the bugs database at http://bugs.mysql.com/, and the MySQL external mailing lists.

• All reported bugs for live versions are entered into the bugs database.

• When we fix a bug, we always try to make a test case for it and include it into our test system to ensure that the bug can never recur without being detected. (About 90% of all fixed bugs have a test case.)

• We create test cases for all new features we add to MySQL.

• Before we start to build a new MySQL release, we ensure that all reported repeatable bugs for the MySQL version (3.23.x, 4.0.x, etc) are fixed. If something is impossible to fix (due to some

internal design decision in MySQL), we document this in the manual. See Section A.8, "Known Issues in MySQL".

- We do a build on all platforms for which we support binaries (15+ platforms) and run our test suite and benchmark suite on all of them.

- We do not publish a binary for a platform for which the test or benchmark suite fails. If the problem is due to a general error in the source, we fix it and do the build plus tests on all systems again from scratch.

- The build and test process takes 2-3 days. If we receive a report regarding a fatal bug during this process (for example, one that causes a core dump), we fix the problem and restart the build process.

- After publishing the binaries on http://dev.mysql.com/, we send out an announcement message to the `mysql` and `announce` mailing lists. See Section 1.7.1.1, "The MySQL Mailing Lists". The announcement message contains a list of all changes to the release and any known problems with the release. The Known Problems section in the release notes has been needed for only a handful of releases.

- To quickly give our users access to the latest MySQL features, we do a new MySQL release every 4-8 weeks. Source code snapshots are built daily and are available at http://downloads.mysql.com/snapshots.php.

- If, despite our best efforts, we get any bug reports after the release is done that there was something critically wrong with the build on a specific platform, we fix it at once and build a new `'a'` release for that platform. Thanks to our large user base, problems are found quickly.

- Our track record for making stable releases is quite good. In the last 150 releases, we had to do a new build for fewer than 10 releases. In three of these cases, the bug was a faulty `glibc` library on one of our build machines that took us a long time to track down.

2.1.2.5. MySQL Binaries Compiled by MySQL AB

As a service of MySQL AB, we provide a set of binary distributions of MySQL that are compiled on systems at our site or on systems where supporters of MySQL kindly have given us access to their machines.

In addition to the binaries provided in platform-specific package formats, we offer binary distributions for a number of platforms in the form of compressed `tar` files (`.tar.gz` files). See Section 2.2, "Standard MySQL Installation Using a Binary Distribution".

For Windows distributions, see Section 2.3, "Installing MySQL on Windows".

These distributions are generated using the script `Build-tools/Do-compile`, which compiles the source code and creates the binary `tar.gz` archive using `scripts/make_binary_distribution`.

These binaries are configured and built with the following compilers and options. This information can also be obtained by looking at the variables `COMP_ENV_INFO` and `CONFIGURE_LINE` inside the script `bin/mysqlbug` of every binary `tar` file distribution.

The following binaries are built on MySQL AB development systems:

- Linux 2.4.xx x86 with `gcc` 2.95.3:

```
CFLAGS="-O2   -mcpu=pentiumpro"  CXX=gcc   CXXFLAGS="-O2   -
mcpu=pentiumpro    -felide-constructors"    ./configure    -
-prefix=/usr/local/mysql    --with-extra-charsets=complex    -
-enable-thread-safe-client        --enable-local-infile    -
-enable-assembler              --disable-shared        -
```

```
-with-client-ldflags=-all-static                              -
-with-mysqld-ldflags=-all-static
```

- Linux 2.4.x x86 with `icc` (Intel C++ Compiler 8.1 or later releases):

```
CC=icc CXX=icpc CFLAGS="-O3 -unroll2 -ip -mp -no-gcc -restrict"
CXXFLAGS="-O3 -unroll2 -ip -mp -no-gcc -restrict" ./configure -
-prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data -
-libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex -
-enable-thread-safe-client        --enable-local-infile        -
-enable-assembler                --disable-shared             -
-with-client-ldflags=-all-static                              -
-with-mysqld-ldflags=-all-static    --with-embedded-server   -
-with-innodb
```

Note that versions 8.1 and newer of the Intel compiler have separate drivers for 'pure' C (`icc`) and C++ (`icpc`); if you use `icc` version 8.0 or older for building MySQL, you will need to set `CXX=icc`.

- Linux 2.4.xx Intel Itanium 2 with `ecc` (Intel C++ Itanium Compiler 7.0):

```
CC=ecc    CFLAGS="-O2    -tpp2    -ip    -nolib_inline"    CXX=ecc
CXXFLAGS="-O2    -tpp2    -ip    -nolib_inline"    ./configure    -
-prefix=/usr/local/mysql      --with-extra-charsets=complex      -
-enable-thread-safe-client --enable-local-infile
```

- Linux 2.4.xx Intel Itanium with `ecc` (Intel C++ Itanium Compiler 7.0):

```
CC=ecc    CFLAGS=-tpp1    CXX=ecc    CXXFLAGS=-tpp1    ./configure    -
-prefix=/usr/local/mysql      --with-extra-charsets=complex      -
-enable-thread-safe-client --enable-local-infile
```

- Linux 2.4.xx alpha with `ccc` (Compaq C V6.2-505 / Compaq C++ V6.3-006):

```
CC=ccc CFLAGS="-fast -arch generic" CXX=cxx CXXFLAGS="-fast -
arch   generic   -noexceptions   -nortti"   ./configure   -
-prefix=/usr/local/mysql      --with-extra-charsets=complex     -
-enable-thread-safe-client        --enable-local-infile        -
-with-mysqld-ldflags=-non_shared                              -
-with-client-ldflags=-non_shared --disable-shared
```

- Linux 2.x.xx ppc with `gcc` 2.95.4:

```
CC=gcc        CFLAGS="-O3       -fno-omit-frame-pointer"       CXX=gcc
CXXFLAGS="-O3   -fno-omit-frame-pointer   -felide-constructors   -
fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--localstatedir=/usr/local/mysql/data                         -
-libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex -
-enable-thread-safe-client        --enable-local-infile        -
-disable-shared --with-embedded-server --with-innodb
```

- Linux 2.4.xx s390 with `gcc` 2.95.3:

```
CFLAGS="-O2"    CXX=gcc    CXXFLAGS="-O2    -felide-constructors"
./configure                 --prefix=/usr/local/mysql              -
-with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile               --disable-shared             -
-with-client-ldflags=-all-static                              -
-with-mysqld-ldflags=-all-static
```

- Linux 2.4.xx x86_64 (AMD64) with `gcc` 3.2.1:

```
CXX=gcc        ./configure        --prefix=/usr/local/mysql       -
```

```
-with-extra-charsets=complex     --enable-thread-safe-client    -
-enable-local-infile --disable-shared
```

• Sun Solaris 8 x86 with `gcc` 3.2.3:

```
CC=gcc      CFLAGS="-O3      -fno-omit-frame-pointer"     CXX=gcc
CXXFLAGS="-O3   -fno-omit-frame-pointer   -felide-constructors   -
fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--localstatedir=/usr/local/mysql/data                          -
-libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex -
-enable-thread-safe-client        --enable-local-infile         -
-disable-shared --with-innodb
```

• Sun Solaris 8 SPARC with `gcc` 3.2:

```
CC=gcc      CFLAGS="-O3      -fno-omit-frame-pointer"     CXX=gcc
CXXFLAGS="-O3   -fno-omit-frame-pointer   -felide-constructors   -
fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile --enable-assembler --with-named-z-libs=no -
-with-named-curses-libs=-lcurses --disable-shared
```

• Sun Solaris 8 SPARC 64-bit with `gcc` 3.2:

```
CC=gcc    CFLAGS="-O3    -m64    -fno-omit-frame-pointer"    CXX=gcc
CXXFLAGS="-O3 -m64 -fno-omit-frame-pointer -felide-constructors
-fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile          --with-named-z-libs=no           -
-with-named-curses-libs=-lcurses --disable-shared
```

• Sun Solaris 9 SPARC with `gcc` 2.95.3:

```
CC=gcc      CFLAGS="-O3      -fno-omit-frame-pointer"     CXX=gcc
CXXFLAGS="-O3   -fno-omit-frame-pointer   -felide-constructors   -
fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile          --enable-assembler              -
-with-named-curses-libs=-lcurses --disable-shared
```

• Sun Solaris 9 SPARC with `cc-5.0` (Sun Forte 5.0):

```
CC=cc-5.0 CXX=CC ASFLAGS="-xarch=v9" CFLAGS="-Xa -xstrconst -mt
-D_FORTEC_ -xarch=v9" CXXFLAGS="-noex -mt -D_FORTEC_ -xarch=v9"
./configure            --prefix=/usr/local/mysql             -
-with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile --enable-assembler --with-named-z-libs=no -
-enable-thread-safe-client --disable-shared
```

• IBM AIX 4.3.2 ppc with `gcc` 3.2.3:

```
CFLAGS="-O2  -mcpu=powerpc  -Wa,-many  " CXX=gcc CXXFLAGS="-O2  -
mcpu=powerpc  -Wa,-many  -felide-constructors  -fno-exceptions  -
fno-rtti"      ./configure      --prefix=/usr/local/mysql     -
-with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile --with-named-z-libs=no --disable-shared
```

• IBM AIX 4.3.3 ppc with `xlC_r` (IBM Visual Age C/C++ 6.0):

```
CC=xlc_r CFLAGS="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
CXX=xlC_r    CXXFLAGS  ="-ma   -O2   -qstrict  -qoptimize=2   -
qmaxmem=8192"    ./configure     --prefix=/usr/local/mysql     -
-localstatedir=/usr/local/mysql/data                          -
```

```
-libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex -
-enable-thread-safe-client        --enable-local-infile      -
-with-named-z-libs=no --disable-shared --with-innodb
```

- IBM AIX 5.1.0 ppc with gcc 3.3:

```
CFLAGS="-O2  -mcpu=powerpc  -Wa,-many" CXX=gcc  CXXFLAGS="-O2  -
mcpu=powerpc  -Wa,-many  -felide-constructors  -fno-exceptions  -
fno-rtti"       ./configure       --prefix=/usr/local/mysql       -
-with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile --with-named-z-libs=no --disable-shared
```

- IBM AIX 5.2.0 ppc with xlC_r (IBM Visual Age C/C++ 6.0):

```
CC=xlc_r CFLAGS="-ma  -O2  -qstrict  -qoptimize=2  -qmaxmem=8192"
CXX=xlC_r CXXFLAGS="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
./configure              --prefix=/usr/local/mysql              -
-localstatedir=/usr/local/mysql/data                          -
-libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex -
-enable-thread-safe-client        --enable-local-infile      -
-with-named-z-libs=no  --disable-shared  --with-embedded-server  -
-with-innodb
```

- HP-UX 10.20 pa-risc1.1 with gcc 3.1:

```
CFLAGS="-DHPUX    -I/opt/dce/include    -O3    -fPIC"    CXX=gcc
CXXFLAGS="-DHPUX  -I/opt/dce /include  -felide-constructors  -
fno-exceptions   -fno-rtti   -O3   -fPIC"   ./configure   -
-prefix=/usr/local/mysql     --with-extra-charsets=complex     -
-enable-thread-safe-client --enable-local-infile --with-pthread
--with-named-thread-libs=-ldce     --with-lib-ccflags=-fPIC    -
-disable-shared
```

- HP-UX 11.00 pa-risc with aCC (HP ANSI C++ B3910B A.03.50):

```
CC=cc    CXX=aCC    CFLAGS=+DAportable    CXXFLAGS=+DAportable
./configure               --prefix=/usr/local/mysql            -
-localstatedir=/usr/local/mysql/data                          -
-libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex -
-enable-thread-safe-client        --enable-local-infile      -
-disable-shared --with-embedded-server --with-innodb
```

- HP-UX 11.11 pa-risc2.0 64bit with aCC (HP ANSI C++ B3910B A.03.33):

```
CC=cc   CXX=aCC   CFLAGS=+DD64   CXXFLAGS=+DD64   ./configure   -
-prefix=/usr/local/mysql      --with-extra-charsets=complex     -
-enable-thread-safe-client        --enable-local-infile      -
-disable-shared
```

- HP-UX 11.11 pa-risc2.0 32bit with aCC (HP ANSI C++ B3910B A.03.33):

```
CC=cc    CXX=aCC    CFLAGS="+DAportable"    CXXFLAGS="+DAportable"
./configure               --prefix=/usr/local/mysql            -
-localstatedir=/usr/local/mysql/data                          -
-libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex -
-enable-thread-safe-client        --enable-local-infile      -
-disable-shared --with-innodb
```

- HP-UX 11.22 ia64 64bit with aCC (HP aC++/ANSI C B3910B A.05.50):

```
CC=cc   CXX=aCC   CFLAGS="+DD64   +DSitanium2"   CXXFLAGS="+DD64
+DSitanium2"      ./configure      --prefix=/usr/local/mysql    -
-localstatedir=/usr/local/mysql/data                          -
```

```
-libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex -
-enable-thread-safe-client        --enable-local-infile        -
-disable-shared --with-embedded-server --with-innodb
```

- Apple Mac OS X 10.2 powerpc with `gcc` 3.1:

```
CC=gcc    CFLAGS="-O3    -fno-omit-frame-pointer"    CXX=gcc
CXXFLAGS="-O3  -fno-omit-frame-pointer  -felide-constructors  -
fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile --disable-shared
```

- FreeBSD 4.7 i386 with `gcc` 2.95.4:

```
CFLAGS=-DHAVE_BROKEN_REALPATH            ./configure        -
-prefix=/usr/local/mysql      --with-extra-charsets=complex    -
-enable-thread-safe-client        --enable-local-infile        -
-enable-assembler --with-named-z-libs=not-used --disable-shared
```

- FreeBSD 4.7 i386 using LinuxThreads with `gcc` 2.95.4:

```
CFLAGS="-DHAVE_BROKEN_REALPATH  -D__USE_UNIX98  -D_REENTRANT  -
D_THREAD_SAFE       -I/usr/local/include/pthread/linuxthreads"
CXXFLAGS="-DHAVE_BROKEN_REALPATH -D__USE_UNIX98 -D_REENTRANT  -
D_THREAD_SAFE       -I/usr/local/include/pthread/linuxthreads"
./configure             --prefix=/usr/local/mysql            -
-localstatedir=/usr/local/mysql/data                         -
-libexecdir=/usr/local/mysql/bin  --enable-thread-safe-client  -
-enable-local-infile            --enable-assembler            -
-with-named-thread-libs="-DHAVE_GLIBC2_STYLE_GETHOSTBYNAME_R   -
D_THREAD_SAFE   -I   /usr/local/include/pthread/linuxthreads   -
L/usr/local/lib   -llthread   -llgcc_r"   --disable-shared   -
-with-embedded-server --with-innodb
```

- QNX Neutrino 6.2.1 i386 with `gcc` 2.95.3qnx-nto 20010315:

```
CC=gcc    CFLAGS="-O3    -fno-omit-frame-pointer"    CXX=gcc
CXXFLAGS="-O3  -fno-omit-frame-pointer  -felide-constructors  -
fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile --disable-shared
```

The following binaries are built on third-party systems kindly provided to MySQL AB by other users. These are provided only as a courtesy; MySQL AB does not have full control over these systems, so we can provide only limited support for the binaries built on them.

- SCO Unix 3.2v5.0.7 i386 with `gcc` 2.95.3:

```
CFLAGS="-O3  -mpentium" LDFLAGS=-static CXX=gcc CXXFLAGS="-O3  -
mpentium       -felide-constructors"       ./configure       -
-prefix=/usr/local/mysql      --with-extra-charsets=complex    -
-enable-thread-safe-client        --enable-local-infile        -
-with-named-z-libs=no        --enable-thread-safe-client       -
-disable-shared
```

- SCO UnixWare 7.1.4 i386 with `CC` 3.2:

```
CC=cc CFLAGS="-O" CXX=CC ./configure --prefix=/usr/local/mysql -
-with-extra-charsets=complex      --enable-thread-safe-client   -
-enable-local-infile          --with-named-z-libs=no           -
-enable-thread-safe-client --disable-shared --with-readline
```

- SCO OpenServer 6.0.0 i386 with `CC` 3.2:

```
CC=cc CFLAGS="-O" CXX=CC ./configure --prefix=/usr/local/mysql -
-with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile          --with-named-z-libs=no          -
-enable-thread-safe-client --disable-shared --with-readline
```

- Compaq Tru64 OSF/1 V5.1 732 alpha with `cc`/`cxx` (Compaq C V6.3-029i / DIGITAL C++ V6.1-027):

```
CC="cc -pthread" CFLAGS="-O4 -ansi_alias -ansi_args -fast -
inline speed -speculate all" CXX="cxx -pthread" CXXFLAGS="-O4 -
ansi_alias -fast -inline speed -speculate all -noexceptions -
nortti"        ./configure        --prefix=/usr/local/mysql    -
-with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile  --with-named-thread-libs="-lpthread  -lmach
-lexc -lc" --disable-shared --with-mysqld-ldflags=-all-static
```

- SGI Irix 6.5 IP32 with `gcc` 3.0.1:

```
CC=gcc  CFLAGS="-O3  -fno-omit-frame-pointer"  CXXFLAGS="-O3  -
fno-omit-frame-pointer  -felide-constructors  -fno-exceptions  -
fno-rtti"       ./configure       --prefix=/usr/local/mysql      -
-with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile --disable-shared
```

- FreeBSD/sparc64 5.0 with `gcc` 3.2.1:

```
CFLAGS=-DHAVE_BROKEN_REALPATH               ./configure          -
-prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data -
-libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex -
-enable-thread-safe-client          --enable-local-infile          -
-disable-shared --with-innodb
```

The following compile options have been used for binary packages that MySQL AB provided in the past. These binaries no longer are being updated, but the compile options are listed here for reference purposes.

- Linux 2.2.xx SPARC with `egcs` 1.1.2:

```
CC=gcc        CFLAGS="-O3        -fno-omit-frame-pointer"        CXX=gcc
CXXFLAGS="-O3  -fno-omit-frame-pointer  -felide-constructors  -
fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex    --enable-thread-safe-client    -
-enable-local-infile --enable-assembler --disable-shared
```

- Linux 2.2.x with x686 with `gcc` 2.95.2:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro -
felide-constructors  -fno-exceptions  -fno-rtti"  ./configure  -
-prefix=/usr/local/mysql           --enable-assembler           -
-with-mysqld-ldflags=-all-static       --disable-shared          -
-with-extra-charsets=complex
```

- SunOS 4.1.4 2 sun4c with `gcc` 2.7.2.1:

```
CC=gcc CXX=gcc CXXFLAGS="-O3 -felide-constructors" ./configure -
-prefix=/usr/local/mysql            --disable-shared            -
-with-extra-charsets=complex --enable-assembler
```

- SunOS 5.5.1 (and above) sun4u with `egcs` 1.0.3a or 2.90.27 or

```
gcc 2.95.2 and newer: CC=gcc CFLAGS="-O3" CXX=gcc CXXFLAGS="-O3 -
felide-constructors -fno-exceptions -fno-rtti" ./configure -
-prefix=/usr/local/mysql        --with-low-memory           -
-with-extra-charsets=complex --enable-assembler
```

- SunOS 5.6 i86pc with `gcc` 2.8.1:

```
CC=gcc        CXX=gcc        CXXFLAGS=-O3        ./configure        -
-prefix=/usr/local/mysql        --with-low-memory           -
-with-extra-charsets=complex
```

- BSDI BSD/OS 3.1 i386 with `gcc` 2.7.2.1:

```
CC=gcc CXX=gcc CXXFLAGS=-O ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex
```

- BSDI BSD/OS 2.1 i386 with `gcc` 2.7.2:

```
CC=gcc        CXX=gcc        CXXFLAGS=-O3        ./configure        -
-prefix=/usr/local/mysql --with-extra-charsets=complex
```

- AIX 4.2 with `gcc` 2.7.2.2:

```
CC=gcc        CXX=gcc        CXXFLAGS=-O3        ./configure        -
-prefix=/usr/local/mysql --with-extra-charsets=complex
```

Anyone who has more optimal options for any of the preceding configurations listed can always mail them to the MySQL `internals` mailing list. See Section 1.7.1.1, "The MySQL Mailing Lists".

RPM distributions prior to MySQL 3.22 are user-contributed. Beginning with MySQL 3.22, RPM distributions are generated by MySQL AB.

If you want to compile a debug version of MySQL, you should add `--with-debug` or `--with-debug=full` to the preceding `configure` commands and remove any `-fomit-frame-pointer` options.

2.1.3. How to Get MySQL

Check the MySQL downloads page (http://dev.mysql.com/downloads/) for information about the current version and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see http://dev.mysql.com/downloads/mirrors.html. There you can also find information about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

Our main mirror is located at http://mirrors.sunsite.dk/mysql/.

2.1.4. Verifying Package Integrity Using MD5 Checksums or `GnuPG`

After you have downloaded the MySQL package that suits your needs and before you attempt to install it, you should make sure that it is intact and has not been tampered with. MySQL AB offers three means of integrity checking:

- MD5 checksums

- Cryptographic signatures using `GnuPG`, the GNU Privacy Guard

- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site. If you repeatedly cannot successfully verify the integrity of the package, please notify us about such incidents, including the full package name and the download site you have been using, at <webmaster@mysql.com> or <build@mysql.com>. Do not report downloading problems using the bug-reporting system.

2.1.4.1. Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify with the following command, where package_name is the name of the package you downloaded:

```
shell> md5sum package_name
```

Example:

```
shell> md5sum mysql-standard-4.0.17-pc-linux-i686.tar.gz
60f5fe969d61c8f82e4f7f62657e1f06  mysql-standard-4.0.17-pc-linux-i686.tar.gz
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

Note: Make sure to verify the checksum of the **archive file** (e.g. the .zip or .tar.gz file) and not of the files that are contained inside of the archive!

Note that not all operating systems support the md5sum command. On some, it is simply called md5 and others do not ship it at all. On Linux, it is part of the GNU Text Utilities package, which is available for a wide range of platforms. You can download the source code from http://www.gnu.org/software/textutils/ as well. If you have OpenSSL installed, you can also use the command openssl md5 package_name instead. A DOS/Windows implementation of the md5 command line utility is available from http://www.fourmilab.ch/md5/. A graphical MD5 checking tool is winMd5Sum, which can be obtained from http://www.nullriver.com/index/products/winmd5sum.

2.1.4.2. Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using MD5 checksums, but requires more work.

Beginning with MySQL 4.0.10 (February 2003), MySQL AB started signing downloadable packages with GnuPG (GNU Privacy Guard). GnuPG is an Open Source alternative to the very well-known Pretty Good Privacy (PGP) by Phil Zimmermann. See http://www.gnupg.org/ for more information about GnuPG and how to obtain and install it on your system. Most Linux distributions ship with GnuPG installed by default. For more information about OpenPGP, see http://www.openpgp.org/.

To verify the signature for a specific package, you first need to obtain a copy of MySQL AB's public GPG build key. You can download the key from http://www.keyserver.net/. The key that you want to obtain is named build@mysql.com. Alternatively, you can cut and paste the key directly from the following text:

```
Key ID:
pub  1024D/5072E1F5 2003-02-03
     MySQL Package signing key (www.mysql.com) <build@mysql.com>
Fingerprint: A4A9 4068 76FC BD3C 4567  70C8 8C71 8D3B 5072 E1F5

Public Key (ASCII-armored):
```

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1.0.6 (GNU/Linux)

-----END PGP PUBLIC KEY BLOCK-----
```

You can import the build key into your personal public GPG keyring by using `gpg --import`. For example, if you save the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
```

See the GPG documentation for more information on how to work with public keys.

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension. For example:

Distribution file	mysql-standard-4.0.17-pc-linux-i686.tar.gz
Signature file	mysql-stand-ard-4.0.17-pc-linux-i686.tar.gz.asc

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

Example:

```
shell> gpg --verify mysql-standard-4.0.17-pc-linux-i686.tar.gz.asc
gpg: Warning: using insecure memory!
gpg: Signature made Mon 03 Feb 2003 08:50:39 PM MET
using DSA key ID 5072E1F5
```

```
gpg: Good signature from
     "MySQL Package signing key (www.mysql.com) <build@mysql.com>"
```

The Good signature message indicates that everything is all right. You can ignore the insec-
ure memory warning.

2.1.4.3. Signature Checking Using `RPM`

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and
MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-4.0.10-0.i386.rpm
MySQL-server-4.0.10-0.i386.rpm: md5 gpg OK
```

Note: If you are using RPM 4.1 and it complains about (GPG) NOT OK (MISSING KEYS:
GPG#5072e1f5), even though you have imported the MySQL public build key into your own
GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your
personal GPG keyring (or GPG itself). Rather, it maintains its own keyring because it is a system-
wide application and a user's GPG public keyring is a user-specific file. To import the MySQL pub-
lic key into the RPM keyring, first obtain the key as described in the previous section. Then use rpm
--import to import the key. For example, if you have the public key stored in a file named
mysql_pubkey.asc, import it using this command:

```
shell> rpm --import mysql_pubkey.asc
```

If you need to obtain the MySQL public key, see Section 2.1.4.2, "Signature Checking Using
GnuPG".

2.1.5. Installation Layouts

This section describes the default layout of the directories created by installing binary or source dis-
tributions provided by MySQL AB. If you install a distribution provided by another vendor, some
other layout might be used.

On Windows, the default installation directory is C:\mysql. With MySQL version 4.1.5 and high-
er, this has changed to C:\Program Files\MySQL\MySQL Server 4.1, where 4.1 is the
major version of the installation. The folder has the following subdirectories:

Directory	Contents of Directory
bin	Client programs and the mysqld server
data	Log files, databases
Docs	Documentation
examples	Example programs and scripts
include	Include (header) files
lib	Libraries
scripts	Utility scripts
share	Error message files

Installations created from Linux RPM distributions result in files under the following system direct-
ories:

Directory	Contents of Directory

/usr/bin	Client programs and scripts
/usr/sbin	The mysqld server
/var/lib/mysql	Log files, databases
/usr/share/doc/packages	Documentation
/usr/include/mysql	Include (header) files
/usr/lib/mysql	Libraries
/usr/share/mysql	Error message and character set files
/usr/share/sql-bench	Benchmarks

On Unix, a `tar` file binary distribution is installed by unpacking it at the installation location you choose (typically /usr/local/mysql) and creates the following directories in that location:

Directory	Contents of Directory
bin	Client programs and the mysqld server
data	Log files, databases
docs	Documentation, ChangeLog
include	Include (header) files
lib	Libraries
scripts	mysql_install_db
share/mysql	Error message files
sql-bench	Benchmarks

A source distribution is installed after you configure and compile it. By default, the installation step installs files under /usr/local, in the following subdirectories:

Directory	Contents of Directory
bin	Client programs and scripts
include/mysql	Include (header) files
info	Documentation in Info format
lib/mysql	Libraries
libexec	The mysqld server
share/mysql	Error message files
sql-bench	Benchmarks and crash-me test
var	Databases and log files

Within an installation directory, the layout of a source installation differs from that of a binary installation in the following ways:

- The mysqld server is installed in the libexec directory rather than in the bin directory.

- The data directory is var rather than data.

- mysql_install_db is installed in the bin directory rather than in the scripts directory.

- The header file and library directories are include/mysql and lib/mysql rather than include and lib.

You can create your own binary installation from a compiled source distribution by executing the

`scripts/make_binary_distribution` script from the top directory of the source distribution.

2.2. Standard MySQL Installation Using a Binary Distribution

The next several sections cover the installation of MySQL on platforms where we offer packages using the native packaging format of the respective platform. (This is also known as performing a "binary install.") However, binary distributions of MySQL are available for many other platforms as well. See Section 2.7, "Installing MySQL on Other Unix-Like Systems" for generic installation instructions for these packages that apply to all platforms.

See Section 2.1, "General Installation Issues" for more information on what other binary distributions are available and how to obtain them.

2.3. Installing MySQL on Windows

A native Windows version of MySQL has been available from MySQL AB since version 3.21 and represents a sizable percentage of the daily downloads of MySQL. This section describes the process for installing MySQL on Windows.

With the release of MySQL 4.1.5, MySQL AB has introduced a new installer for the Windows version of MySQL, combined with a new GUI Configuration Wizard. This combination automatically installs MySQL, creates an option file, starts the server, and secures the default user accounts.

If you have installed a version of MySQL prior to version 4.1.5, you must perform the following steps:

1. Obtain and install the distribution.

2. Set up an option file if necessary.

3. Select the server that you want to use.

4. Start the server.

5. Assign passwords to the initial MySQL accounts.

This process also must be followed with newer MySQL installations where the installation package does not include an installer.

MySQL for Windows is available in two distribution formats:

• The binary distribution contains a setup program that installs everything you need so that you can start the server immediately.

• The source distribution contains all the code and support files for building the executables using the VC++ 6.0 compiler.

Generally speaking, you should use the binary distribution. It's simpler, and you need no additional tools to get MySQL up and running.

This section describes how to install MySQL on Windows using a binary distribution. To install using a source distribution, see Section 2.8.6, "Installing MySQL from Source on Windows".

2.3.1. Windows System Requirements

To run MySQL on Windows, you need the following:

- A 32-bit Windows operating system such as 9x, Me, NT, 2000, XP, or Windows Server 2003.

  A Windows NT based operating system (NT, 2000, XP, 2003) permits you to run the MySQL server as a service. The use of a Windows NT based operating system is strongly recommended. See Section 2.3.12, "Starting MySQL as a Windows Service".

- TCP/IP protocol support.

- A copy of the MySQL binary distribution for Windows, which can be downloaded from http://dev.mysql.com/downloads/. See Section 2.1.3, "How to Get MySQL".

  Note: If you download the distribution via FTP, we recommend the use of an adequate FTP client with a resume feature to avoid corruption of files during the download process.

- A tool that can read `.zip` files, to unpack the distribution file.

- Enough space on the hard drive to unpack, install, and create the databases in accordance with your requirements (generally a minimum of 200 megabytes is recommended.)

You may also have the following optional requirements:

- If you plan to connect to the MySQL server via ODBC, you also need a Connector/ODBC driver. See Section 24.1, "MySQL Connector/ODBC".

- If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer filesystem. Don't forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See Section 13.1.5, "`CREATE TABLE` Syntax".

2.3.2. Choosing An Installation Package

Starting with MySQL version 4.1.5, there are three install packages to choose from when installing MySQL on Windows. The Packages are as follows:

- **The Essentials Package**: This package has a filename similar to `mysql-essential-4.1.9-win32.msi` and contains the minimum set of files needed to install MySQL on Windows, including the Configuration Wizard. This package does not include optional components such as the embedded server and benchmark suite.

- **The Complete Package**: This package has a filename similar to `mysql-4.1.9-win32.zip` and contains all files needed for a complete Windows installation, including the Configuration Wizard. This package includes optional components such as the embedded server and benchmark suite.

- **The Noinstall Archive**: This package has a filename similar to `mysql-noinstall-4.1.9-win32.zip` and contains all the files found in the Complete install package, with the exception of the Configuration Wizard. This package does not include an automated installer, and must be manually installed and configured.

The Essentials package is recommended for most users.

Your choice of install package affects the installation process you must follow. If you choose to install either the Essentials or Complete install packages, see Section 2.3.3, "Installing MySQL with the Automated Installer". If you choose to install MySQL from the Noinstall archive, see Section 2.3.6, "Installing MySQL from a Noinstall Zip Archive".

2.3.3. Installing MySQL with the Automated Installer

Starting with MySQL 4.1.5, users can use the new MySQL Installation Wizard and MySQL Configuration Wizard to install MySQL on Windows. The MySQL Installation Wizard and MySQL Configuration Wizard are designed to install and configure MySQL in such a way that new users can immediately get started using MySQL.

The MySQL Installation Wizard and MySQL Configuration Wizard are available in the Essentials and Complete install packages, and are recommended for most standard MySQL installations. Exceptions include users who need to install multiple instances of MySQL on a single server and advanced users who want complete control of server configuration.

If you are installing a version of MySQL prior to MySQL 4.1.5, please follow the instructions for installing MySQL from the Noinstall installation package. See Section 2.3.6, "Installing MySQL from a Noinstall Zip Archive".

2.3.4. Using the MySQL Installation Wizard

2.3.4.1. Introduction

MySQL Installation Wizard is a new installer for the MySQL server that uses the latest installer technologies for Microsoft Windows. The MySQL Installation Wizard, in combination with the MySQL Configuration Wizard, allows a user to install and configure a MySQL server that is ready for use immediately after installation.

The MySQL Installation Wizard is the standard installer for all MySQL server distributions, version 4.1.5 and higher. Users of previous versions of MySQL need to manually shut down and remove their existing MySQL installations before installing MySQL with the MySQL Installation Wizard. See Section 2.3.4.7, "Upgrading MySQL" for more information on upgrading from a previous version.

Microsoft has included an improved version of their Microsoft Windows Installer (MSI) in the recent versions of Windows. Using the MSI has become the de-facto standard for application installations on Windows 2000, Windows XP, and Windows Server 2003. The MySQL Installation Wizard makes use of this technology to provide a smoother and more flexible installation progress.

The Microsoft Windows Installer Engine was updated with the release of Windows XP; those using a previous version of Windows can reference this Microsoft Knowledge Base article [http://support.microsoft.com/default.aspx?scid=kb;EN-US;292539] for information on upgrading to the latest version of the Windows Installer Engine.

Further, Microsoft has introduced the WiX (Windows Installer XML) tool set recently. It is the first highly acknowledged Open Source project from Microsoft. We switched to WiX because it is an Open Source project and it allows us to handle the complete Windows installation process in a flexible way with scripts.

Improving the MySQL Installation Wizard depends on the support and feedback of users like you. If you find that the MySQL Installation Wizard is lacking some feature important to you, or if you discover a bug, please use our MySQL Bug System [http://bugs.mysql.com] to request features or report problems.

2.3.4.2. Downloading and Starting the MySQL Installation Wizard

The MySQL server install packages can be downloaded from http://dev.mysql.com/downloads/. If the package you download is contained within a Zip archive, you need to extract the archive first.

The process for starting the wizard depends on the contents of the install package you download. If there is a `setup.exe` file present, double-click it to start the install process. If there is a `.msi` file present, double-click it to start the install process.

2.3.4.3. Choosing an Install Type

There are up three installation types available: `Typical`, `Complete`, and `Custom`.

The `Typical` installation type installs the MySQL server, the `mysql` command-line client, and the command-line utilities. The command-line clients and utilities include `mysqldump`, `myis-amchk`, and several other tools to help you manage the MySQL server.

The `Complete` installation type installs all components included in the installation package. The full installation package includes components such as the embedded server library, the benchmark suite, support scripts, and documentation.

The `Custom` installation type gives you complete control over which packages you wish to install and the installation path that is used. See Section 2.3.4.4, "The Custom Install Dialog" for more information on performing a custom install.

If you choose the `Typical` or `Complete` installation types and click the Next button, you advance to the confirmation screen to confirm your choices and begin the installation. If you choose the `Custom` installation type and click the Next button, you advance to the custom install dialog, described in Section 2.3.4.4, "The Custom Install Dialog"

2.3.4.4. The Custom Install Dialog

If you wish to change the installation path or the specific components that are installed by the MySQL Installation Wizard, you should choose the `Custom` installation type.

All available components are listed in a tree view on the left side of the custom install dialog. Components that are not installed have a red X icon, components that are installed have a gray icon. To change whether a component is installed, click on the component's icon and choose an new option from the drop-down list that appears.

You can change the default installation path by clicking the Change... button to the right of the displayed installation path.

After choosing your install components and installation path, click the Next button to advance to the confirmation dialog.

2.3.4.5. The Confirmation Dialog

Once you choose an installation type and optionally choose your installation components, you advance to the confirmation dialog. Your installation type and installation path are displayed for you to review.

To install MySQL if you are satisfied with your settings, click the Install button. To change your settings, click the Back button. To exit the MySQL Installation Wizard without installing MySQL, click the Cancel button.

After installation is complete, you are given the option of registering with the MySQL web site. Registration gives you access to post in the MySQL forums at forums.mysql.com [http://forums.mysql.com], along with the ability to report bugs at bugs.mysql.com [http://bugs.mysql.com] and to subscribe to the newsletter. The final screen of the installer provides a summary of the installation and gives you the option to launch the MySQL Configuration Wizard, which you can use to create a configuration file, install the MySQL service, and configure security.

2.3.4.6. Changes Made by MySQL Installation Wizard

Once you click the Install button, the MySQL Installation Wizard begins the installation process and makes certain changes to your system which are described in the sections that follow.

Changes to the Registry

The MySQL Installation Wizard creates one Windows registry key in a typical install situation, located in `HKEY_LOCAL_MACHINE\SOFTWARE\MySQL AB`.

The MySQL Installation Wizard creates a key named after the major version of the server that is being installed, such as `MySQL Server 4.1`. It contains two string values, `Location` and `Version`. The `Location` string contains the path to the installation directory. In a default installation it contains `C:\Program Files\MySQL\MySQL Server 4.1\`. The `Version` string contains the release number. For example, for an installation of MySQL Server 4.1.5 the key contains a value of `4.1.5`.

These registry keys are used to help external tools identify the installed location of the MySQL server, preventing a complete scan of the hard-disk to determine the installation path of the MySQL server. The registry keys are not required to run the server and when using the `noinstall` Zip archive the registry keys are not created.

Changes to the Start Menu

The MySQL Installation Wizard creates a new entry in the Windows Start menu under a common MySQL menu heading named after the major version of MySQL that you have installed. For example, if you install MySQL 4.1, the MySQL Installation Wizard creates a MySQL Server 4.1 section in the start menu.

The following entries are created within the new Start menu section:

- `MySQL Command Line Client`: This is a shortcut to the `mysql` command-line client and is configured to connect as the `root` user. The shortcut prompts for a `root` user password when connecting.

- `MySQL Server Instance Config Wizard`: This is a shortcut to the MySQL Configuration Wizard. Use this shortcut to configure a newly installed server, or to re-configure an existing server.

- `MySQL Documentation`: This is a link to the MySQL server documentation that is stored locally in the MySQL server installation directory. This option is not available when the MySQL server is installed from the `essential` installation package.

Changes to the File System

The MySQL Installation Wizard by default installs the MySQL server to `C:\Program Files\MySQL\MySQL Server 4.1`, where `Program Files` is the default location for applications in your system, and `4.1` is the major version of your MySQL server. This is the new recommended location for the MySQL server, replacing the previous default location of `c:\mysql`.

By default, all MySQL applications are stored in a common directory at `C:\Program Files\MySQL`, where `Program Files` is the default location for applications in your Windows installation. A typical MySQL installation on a developer machine may look like this:

```
C:\Program Files\MySQL\MySQL Server 4.1
C:\Program Files\MySQL\MySQL Server 5.0
C:\Program Files\MySQL\MySQL Administrator 1.0
C:\Program Files\MySQL\MySQL Query Browser 1.0
```

This approach makes it easier to manage and maintain all MySQL applications installed on a particular system.

2.3.4.7. Upgrading MySQL

From MySQL version 4.1.5, the new MySQL Installation Wizard can perform server upgrades automatically using the upgrade capabilities of MSI. That means you do not need to remove a previous installation manually before installing a new release. The installer automatically shuts down and removes the previous MySQL service before installing the new version.

Automatic upgrades are only available when upgrading between installations that have the same major and minor version numbers. For example, you can upgrade automatically from MySQL 4.1.5 to

MySQL 4.1.6, but not from MySQL 4.1 to MySQL 5.0.

If you are upgrading MySQL version 4.1.4 or earlier to version 4.1.5 or later, you must first manually shut down and remove the older installation before upgrading. Be sure to back up your databases before performing such an upgrade, so that you can restore the databases after the upgrade is completed. It is always recommended that you back up your data before performing any upgrades.

See Section 2.3.15, "Upgrading MySQL on Windows".

2.3.5. Using the Configuration Wizard

2.3.5.1. Introduction

The MySQL Configuration Wizard helps automate the process of configuring your server under Windows. The MySQL Configuration Wizard creates a custom `my.ini` file by asking you a series of questions and then applying your responses to a template to generate a `my.ini` file that is tuned to your installation.

The MySQL Configuration Wizard is included with the MySQL server starting with MySQL version 4.1.5, but is designed to work with MySQL servers versions 4.1 and higher. The MySQL Configuration Wizard is currently available for Windows users only.

MySQL Configuration Wizard is to a large extent the result of feedback MySQL AB has received from many users over a period of several years. However, if you find it's lacking some feature important to you, or if you discover a bug, please use our MySQL Bug System [http://bugs.mysql.com] to request features or report problems.

2.3.5.2. Starting the MySQL Configuration Wizard

The MySQL Configuration Wizard is typically launched from the MySQL Installation Wizard, as the MySQL Installation Wizard exits. You can also launch the MySQL Configuration Wizard by clicking the MySQL Server Instance Config Wizard entry in the MySQL section of the `Start` menu.

In addition, you can navigate to the `bin` directory of your MySQL installation and launch the `MySQLInstanceConfig.exe` file directly.

2.3.5.3. Choosing a Maintenance Option

If the MySQL Configuration Wizard detects an existing `my.ini` file, you have the option of either re-configuring your existing server, or removing the server instance by deleting the `my.ini` file and stopping and removing the MySQL service.

To reconfigure an existing server, choose the `Re-configure Instance` option and click the Next button. Your existing `my.ini` file is renamed to `my timestamp.ini.bak`, where `timestamp` is the date and time the existing `my.ini` file was created. To remove the existing server instance, choose the `Remove Instance` option and click the Next button.

If you choose the `Remove Instance` option, you advance to a confirmation window. Click the Execute button and the MySQL Configuration Wizard stops and removes the MySQL service and deletes the `my.ini` file. The server installation and its `data` folder are not removed.

If you choose the `Re-configure Instance` option, you advance to the `Configuration Type` dialog where you can choose the type of installation you wish to configure.

2.3.5.4. Choosing a Configuration Type

When you start the MySQL Configuration Wizard for a new MySQL installation, or choose the `Re-configure Instance` option for an existing installation, you advance to the `Configuration Type` dialog.

There are two configuration types available: `Detailed Configuration` and `Standard Configuration`. The `Standard Configuration` option is intended for new users who want to get started with MySQL quickly without having to make a lot of decisions in regards to server configuration. The `Detailed Configuration` option is intended for advanced users who want more fine-grained control of server configuration.

If you are new to MySQL and need a server configured as a single-user developer machine the `Standard Configuration` should suit your needs. Choosing the `Standard Configuration` option causes the MySQL Configuration Wizard to automatically set all configuration options with the exception of the `Service Options` and `Security Options`.

The `Standard Configuration` sets options that may be incompatible with systems where there are existing MySQL installations. If you have an existing MySQL installation on your system in addition to the installation you wish to configure, the `Detailed Configuration` option is recommended.

To complete the `Standard Configuration`, please refer to the sections on `Service Options` and `Security Options`, located at Section 2.3.5.11, "The Service Options Dialog" and Section 2.3.5.12, "The Security Options Dialog" respectively.

2.3.5.5. The Server Type Dialog

There are three different server types available to choose from, and the server type you choose affects the decisions the MySQL Configuration Wizard makes with regards to memory, disk, and processor usage.

- `Developer Machine`: Choose this option for a typical desktop workstation where MySQL is intended only for personal use. It is assumed that many other desktop applications are running. The MySQL server is configured to use minimal system resources.

- `Server Machine`: Choose this option for a server machine where the MySQL server is running alongside other server applications such as FTP, email, and web servers. The MySQL server is configured to use a medium portion of the system resources.

- `Dedicated MySQL Server Machine`: Choose this option for a server machine that is intended to run only the MySQL server. It is assumed that no other applications are running. The MySQL server is configured to use all available system resources.

2.3.5.6. The Database Usage Dialog

The `Database Usage` dialog allows you to indicate the table handlers you expect to use when creating MySQL tables. The option you choose determines whether the InnoDB table handler is available and what percentage of the server resources are available to InnoDB.

- `Multifunctional Database`: This option enables both the InnoDB and MyISAM table handlers and divides resources evenly between the two. This option is recommended for users that use both table handlers on a regular basis.

- `Transactional Database Only`: This option enables both the InnoDB and MyISAM table handlers but dedicates most server resources toward the InnoDB table handler. This option is recommended for users that use InnoDB almost exclusively and make only minimal use of MyISAM.

- `Non-Transactional Database Only`: This option disables the InnoDB table handler completely and dedicates all server resources to the MyISAM table handler. This option is recommended for users who do not use InnoDB.

2.3.5.7. The InnoDB Tablespace Dialog

Some users may want to locate the InnoDB tablespace files in a different location than the MySQL server data directory. Placing the tablespace files in a separate location can be desirable if your system has a higher capacity or higher performance storage device available, such as a RAID storage system.

To change the default location for the InnoDB tablespace files, choose a new drive from the drop-down list of drive letters and choose a new path from the drop-down list of paths. To create a custom path, click the ... button.

If you are modifying the configuration of an existing server, you must click the Modify button before you change the path. In this situation you have to manually move the existing tablespace files to the new location before starting the server.

2.3.5.8. The Concurrent Connections Dialog

It is important to set a limit to the number of concurrent connections to the MySQL server that can be established to prevent the server from running out of resources. The `Concurrent Connections` dialog allows you to choose the expected usage of your server, and sets the limit for concurrent connections accordingly. It is also possible to manually set the concurrent connection limit.

- `Decision Support (DSS)/OLAP`: Choose this option if your server does not require a large number of concurrent connections. The maximum number of connections is set at 100, with an average of 20 concurrent connections assumed.

- `Online Transaction Processing (OLTP)`: Choose this option if your server requires a large number of concurrent connections. The maximum number of connections is set at 500.

- `Manual Setting`: Choose this option to manually set the maximum number of concurrent connections to the server. Choose the number of concurrent connections from the drop-down box provided, or type the maximum number of connections into the drop-down box if the number you desire is not listed.

2.3.5.9. The Networking Options Dialog

Use the `Networking Options` dialog to enable or disable TCP/IP networking and to configure the port number that is used to connect to the MySQL server.

TCP/IP networking is enabled by default. To disable TCP/IP networking, uncheck the box next to the `Enable TCP/IP Networking` option.

Port 3306 is used by default. To change the port used to access MySQL, choose a new port number from the drop-down box or type a new port number directly into the drop-down box. If the port number you choose is in use you are prompted to confirm your choice of port number.

2.3.5.10. The Character Set Dialog

The MySQL server supports multiple character sets and it is possible to set a default server character set that is applied to all tables, columns, and databases unless overridden. Use the `Character Set` dialog to change the default character set of the MySQL server.

- `Standard Character Set`: Choose this option if you want to use `Latin1` as the default server character set. `Latin1` is used for English and many Western European languages.

- `Best Support For Multilingualism`: Choose this option if you want to use `UTF8` as the default server character set. `UTF8` can store characters from many different languages in a single character set.

- `Manual Selected Default Character Set / Collation`: Choose this option if you want to pick the server's default character set manually. Choose the desired character set

from the provided drop-down list.

2.3.5.11. The Service Options Dialog

On Windows NT based platforms, the MySQL server can be installed as a service. When installed as a service, the MySQL server can be started automatically during system startup, and even restarted automatically by Windows in the event of a service failure.

The MySQL Configuration Wizard installs the MySQL server as a service by default, using the service name `MySQL`. If you do not wish to install the service, un-check the box next to the `Install As Windows Service` option. You can change the service name by picking a new service name from the drop-down box provided or by typing a new service name into the drop-down box.

To install the MySQL server as a service but not have it started automatically at startup, un-check the box next to the `Launch the MySQL Server automatically` option.

2.3.5.12. The Security Options Dialog

It is strongly recommended that you set a `root` password for your MySQL server, and the MySQL Configuration Wizard requires you set a `root` password by default. If you do not wish to set a `root` password, un-check the box next to the `Modify Security Settings` option.

To set the `root` password, type the desired password into both the `New root password` and `Confirm` boxes. If you are re-configuring an existing server, you also need to enter the existing `root` password into the `Current root password` box.

To prevent `root` logins from across the network, check the box next to the `Root may only connect from localhost` option. This increases the security of your `root` account.

To create an anonymous user account, check the box next to the `Create An Anonymous Account` option. Creating an anonymous account can decrease server security and cause login and permission difficulties and is not recommended.

2.3.5.13. The Confirmation Dialog

The final dialog in the MySQL Configuration Wizard is the `Confirmation Dialog`. To start the configuration process, click the Execute button. To return to a previous dialog, click the Back button. To exit the MySQL Configuration Wizard without configuring the server, click the Cancel button.

After you click the Execute button, the MySQL Configuration Wizard performs a series of tasks with progress displayed onscreen as the tasks are performed.

The MySQL Configuration Wizard firsts determines various configuration file options based on your choices using a template prepared by MySQL AB developers and engineers. This template is named `my-template.ini` and is located in your server installation directory.

The MySQL Configuration Wizard then writes these options to a `my.ini` file. The final location of the `my.ini` file is displayed next to the `Write configuration file` task.

If you chose to create a service for the MySQL server the MySQL Configuration Wizard creates and starts the service. If you are re-configuring an existing service, the MySQL Configuration Wizard restarts the service to apply your configuration changes.

If you chose to set a `root` password, the MySQL Configuration Wizard connects to the server, sets your new `root` password and applies any other security settings you may have selected.

After the MySQL Configuration Wizard has completed its tasks, a summary is shown. Click the Finish button to exit the MySQL Configuration Wizard.

2.3.5.14. The Location of the my.ini File

In MySQL installations prior to version 4.1.5 it was customary to name the server configuration file `my.cnf` or `my.ini` and locate the file either at `c:\my.cnf` or `c:\Windows\my.ini`.

The new MySQL Configuration Wizard places the `my.ini` file in the installation directory of the MySQL server. This helps associate configuration files with particular server instances.

To ensure that the MySQL server knows where to look for the `my.ini` file, an argument similar to this is passed to the MySQL server as part of the service installation: `--defaults-file="C:\Program Files\MySQL\MySQL Server 4.1\my.ini"`, where `C:\Program Files\MySQL\MySQL Server 4.1` is replaced with the installation path to the MySQL Server.

The `--defaults-file` instructs the MySQL server to read the specified file for configuration options.

2.3.5.15. Editing The my.ini File

To modify the `my.ini` file, open it with a text editor and make any necessary changes. You can also modify the server configuration with the MySQL Administrator [http://www.mysql.com/products/administrator/] utility.

MySQL clients and utilities such as the `mysql` command-line client and `mysqldump` are not able to locate the `my.ini` file located in the server installation directory. To configure the client and utility applications, create a new `my.ini` file in the `c:\Windows` directory.

2.3.6. Installing MySQL from a Noinstall Zip Archive

Users who are installing from the Noinstall package, or who are installing a version of MySQL prior to 4.1.5 can use the instructions in this section to manually install MySQL. If you are installing a version prior to 4.1.5 with an install package that includes a Setup program, substitute running the Setup program for extracting the archive.

The process for installing MySQL from a Zip archive is as follows:

1. Extract the archive to the desired install directory.

2. Create an option file.

3. Choose a MySQL server type.

4. Start the MySQL server.

5. Secure the default user accounts.

This process is described in the sections that follow.

2.3.7. Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to Section 2.3.15, "Upgrading MySQL on Windows" before beginning the upgrade process.

2. If you are using a Windows NT-based operating system such as Windows NT, Windows 2000, Windows XP, or Windows Server 2003, make sure that you are logged in as a user with administrator privileges.

3. Choose an installation location. Traditionally the MySQL server is installed at `C:\mysql`, and the new MySQL Installation Wizard installs MySQL to `C:\Program Files\MySQL`. If

you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See Section 2.3.8, "Creating an Option File".

4. Extract the install archive to the chosen installation location using your preferred Zip archive tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs you can move the contents of the subfolder into the chosen installation location.

2.3.8. Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\mysql` and `C:\mysql\data`).

- You need to tune the server settings. For example, to use the `InnoDB` transactional tables in MySQL 3.23, you must manually add some extra lines to the option file, as described in Section 15.4, "InnoDB Configuration". (As of MySQL 4.0, `InnoDB` creates its data files and log files in the data directory by default. This means you need not configure `InnoDB` explicitly. You may still do so if you wish, and an option file is useful in this case, too.)

When the MySQL server starts on Windows, it looks for options in two files: the `my.ini` file in the Windows directory, and the `C:\my.cnf` file. The Windows directory typically is named something like `C:\WINDOWS` or `C:\WinNT`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options first in the `my.ini` file, then in the `my.cnf` file. However, to avoid confusion, it's best if you use only one file. If your PC uses a boot loader where the `C:` drive isn't the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

You can also make use of the example option files included with your MySQL distribution. Look in your install directory for files such as my-small.cnf, my-medium.cnf, my-large.cnf, etc., which you can rename and copy to the appropriate location for use as a base configuration file.

An option file can be created and modified with any text editor, such as the `Notepad` program. For example, if MySQL is installed at `E:\mysql` and the data directory is located at `E:\mydata\data`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` parameters:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Note that Windows pathnames are specified in option files using forward slashes rather than backslashes. If you do use backslashes, you must double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

On Windows, the MySQL installer places the data directory directly under the directory where you install MySQL. If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, by default, the installer places MySQL in `C:\mysql` and the data directory in `C:\mysql\data`. If you want to use a data directory of `E:\mydata`, you must do two things:

- Move the data directory from `C:\mysql\data` to `E:\mydata`.

- Use a `--datadir` option to specify the new data directory location each time you start the server.

2.3.9. Selecting a MySQL Server type

Starting with MySQL 3.23.38, the Windows distribution includes both the normal and the MySQL-Max server binaries.

Up through the early releases of MySQL 4.1, the servers included in Windows distributions are named like this:

Binary	Description
mysqld	Compiled with full debugging and automatic memory allocation checking, and `InnoDB` and `BDB` tables.
mysqld-opt	Optimized binary. From version 4.0 on, `InnoDB` is enabled. Before 4.0, this server includes no transactional table support.
mysqld-nt	Optimized binary for Windows NT, 2000, and XP with support for named pipes.
mysqld-max	Optimized binary with support for `InnoDB` and `BDB` tables.
mysqld-max-nt	Like `mysqld-max`, but compiled with support for named pipes.

We have found that the server with the most generic name (`mysqld`) is the one that many users are likely to choose by default. However, that is also the server that results in the highest memory and CPU use due to the inclusion of full debugging support. The server named `mysqld-opt` is a better general-use server choice to make instead if you don't need debugging support and don't want the maximal feature set offered by the `-max` servers or named pipe support offered by the `-nt` servers.

To make it less likely that the debugging server would be chosen inadvertently, some name changes were made from MySQL 4.1.2 to 4.1.4: `mysqld` has been renamed to `mysqld-debug` and `mysqld-opt` has been renamed to `mysqld`. Thus, the server that includes debugging support indicates that in its name, and the server named `mysqld` is an efficient default choice. The other servers still have their same names. The resulting servers are named like this:

Binary	Description
mysqld-debug	Compiled with full debugging and automatic memory allocation checking, and `InnoDB` and `BDB` tables.
mysqld	Optimized binary with `InnoDB` support.
mysqld-nt	Optimized binary for Windows NT, 2000, and XP with support for named pipes.
mysqld-max	Optimized binary with support for `InnoDB` and `BDB` tables.
mysqld-max-nt	Like `mysqld-max`, but compiled with support for named pipes.

The name changes were not both instituted at the same time. If you have MySQL 4.1.2 or 4.1.3, it might be that you have a server named `mysqld-debug` but not one named `mysqld`. In this case,

you should have a server `mysqld-opt`, which you should choose as your default server unless you need maximal features, named pipes, or debugging support.

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

As of MySQL 4.0, all Windows servers have support for symbolic linking of database directories. Before MySQL 4.0, only the debugging and Max server versions include this feature.

MySQL supports TCP/IP on all Windows platforms. The `mysqld-nt` and `mysql-max-nt` servers support named pipes on Windows NT, 2000, XP, and 2003. However, the default is to use TCP/IP regardless of the platform. (Named pipes are slower than TCP/IP in many Windows configurations.)

Named pipe use is subject to these conditions:

- Starting from MySQL 3.23.50, named pipes are enabled only if you start the server with the `--enable-named-pipe` option. It is necessary to use this option explicitly because some users have experienced problems shutting down the MySQL server when named pipes were used.

- Named pipe connections are allowed only by the `mysqld-nt` or `mysqld-max-nt` servers, and only if the server is run on a version of Windows that supports named pipes (NT, 2000, XP, 2003).

- These servers can be run on Windows 98 or Me, but only if TCP/IP is installed; named pipe connections cannot be used.

- These servers can not be run on Windows 95.

Note: Most of the examples in reference manual use `mysqld` as the server name. If you choose to use a different server, such as `mysqld-nt`, make the appropriate substitutions in the commands that are shown in the examples.

2.3.10. Starting the Server for the First Time

On Windows 95, 98, or Me, MySQL clients always connect to the server using TCP/IP. (This allows any machine on your network to connect to your MySQL server.) Because of this, you must make sure that TCP/IP support is installed on your machine before starting MySQL. You can find TCP/IP on your Windows CD-ROM.

Note that if you are using an old Windows 95 release (for example, OSR2), it's likely that you have an old Winsock package; MySQL requires Winsock 2! You can get the newest Winsock from http://www.microsoft.com/. Windows 98 has the new Winsock 2 library, so it is unnecessary to update the library.

On NT-based systems such as Windows NT, 2000, XP, or 2003, clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named pipe connections. To get MySQL to work with TCP/IP on Windows NT 4, you must install service pack 3 (or newer).

In MySQL versions 4.1 and higher, Windows servers also support shared-memory connections if started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=memory` option.

For information about which server binary to run, see Section 2.3.9, "Selecting a MySQL Server type".

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The examples in these sections assume that MySQL is installed under the default location of

`C:\mysql`. Adjust the pathnames shown in the examples if you have MySQL installed in a different location.

Testing is best done from a command prompt in a console window (a "DOS window"). This way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

`C:\> C:\mysql\bin\mysqld --console`

For servers that include `InnoDB` support, you should see the following messages as the server starts:

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25  InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '4.0.14-log'  socket: ''  port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\mysql\data` by default). The error log is the file with the `.err` extension.

Note: The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.9, "Post-Installation Setup and Testing".

2.3.11. Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the `mysqld` server from the command line, you should start a console window (a "DOS window") and enter this command:

`C:\> C:\Program Files\MySQL\MySQL Server 4.1\bin\mysqld`

The path used in the preceding example may vary depending on the install location of MySQL on your system.

On non-NT versions of Windows, this starts `mysqld` in the background. That is, after the server starts, you should see another command prompt. If you start the server this way on Windows NT, 2000, XP, or 2003, the server runs in the foreground and no command prompt appears until the server exits. Because of this, you should open another console window to run client programs while the server is running.

You can stop the MySQL server by executing this command:

```
C:\> C:\Program Files\MySQL\MySQL Server 4.1\bin\mysqladmin -u root shutdown
```

This invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the `C:\mysql\data` directory. It is the file with a suffix of `.err`. You can also try to start the server as `mysqld --console`; in this case, you may get some useful information on the screen that may help solve the problem.

The last option is to start `mysqld` with `--standalone --debug`. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See Section F.1.2, "Creating Trace Files".

Use `mysqld --verbose --help` to display all the options that `mysqld` understands. (Prior to MySQL 4.1, omit the `--verbose` option.)

2.3.12. Starting MySQL as a Windows Service

On the NT family (Windows NT, 2000, XP, 2003), the recommended way to run MySQL is to install it as a Windows service. With the MySQL server installed as a service, Windows starts and stops it server automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility.

The `Services` utility (the Windows `Service Control Manager`) can be found in the Windows `Control Panel` (under `Administrative Tools` on Windows 2000, XP, and Server 2003). It is advisable to close the `Services` utility while performing server installation or removal operations from this command line. This prevents some odd errors.

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> C:\mysql\bin\mysqladmin -u root shutdown
```

This invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
C:\> mysqld --install
```

If you have problems installing `mysqld` as a service using just the server name, try installing it using its full pathname. For example:

```
C:\> C:\mysql\bin\mysqld --install
```

The service-installation command does not start the server. Instructions for that are given later in

this section.

Before MySQL 4.0.2, no command-line arguments can be given following the `--install` option. MySQL 4.0.2 and up offers limited support for additional arguments:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.

- As of MySQL 4.0.3, if a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name` to specify the name of an option file from which the server should read options when it starts.

  It is possible to use a single option other than `--defaults-file`, but this is discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file. Also, in MySQL 5.0, use of an option different from `--defaults-file` is not supported until 5.0.3.

- As of MySQL 5.0.1, you can also specify a `--local-service` option following the service name. This causes the server to run using the `LocalService` Windows account that has limited system privileges. This account is available only for Windows XP or newer. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the a service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.

- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the group that has the same name as the service, and reads options from the standard option files.

  As of MySQL 4.0.17, the server also reads options from the `[mysqld]` group from the standard option files. This allows you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the same name as a service for use by the server installed with that service name.

- If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options only from the `[mysqld]` group of the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> C:\mysql\bin\mysqld --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (`MySQL`) is given after the `--install` option. If no `--defaults-file` option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` option is present, the server reads options from the `[mysqld]` option group, but only from the named file.

You can also specify options as "`Start parameters`" in the Windows `Services` utility before you start the MySQL service.

Note: Prior to MySQL 4.0.17, a server installed as a Windows service has problems starting if its pathname or the service name contains spaces. For this reason, with older versions, avoid installing MySQL in a directory such as `C:\Program Files` or using a service name containing spaces.

Once a MySQL server has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the `Services` utility, or by using the command `NET START MySQL`. The `NET` command is not case sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\mysql\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the `Services` utility, the command `NET STOP MySQL`, or the command `mysqladmin shutdown`.

From MySQL 3.23.44 on, you have the choice of installing the server as a `Manual` service if you don't wish the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> C:\mysql\bin\mysqld --install-manual
```

To remove a server that is installed as a service, first stop it if it is running. Then use the `--remove` option to remove it:

```
C:\> C:\mysql\bin\mysqld --remove
```

For MySQL versions older than 3.23.49, one problem with automatic MySQL service shutdown is that Windows waited only for a few seconds for the shutdown to complete, then killed the database server process if the time limit was exceeded. This had the potential to cause problems. (For example, the `InnoDB` storage engine would have to perform crash recovery at the next startup.) Starting from MySQL 3.23.49, Windows waits longer for the MySQL server shutdown to complete. If you notice this still is not enough for your installation, it is safest not to run the MySQL server as a service. Instead, start it from the command-line prompt, and stop it with `mysqladmin shutdown`.

This change to tell Windows to wait longer when stopping the MySQL server works for Windows 2000 and XP. It does not work for Windows NT, where Windows waits only 20 seconds for a service to shut down, and after that kills the service process. You can increase this default by opening the Registry Editor `\winnt\system32\regedt32.exe` and editing the value of `Wait-ToKillServiceTimeout` at `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control` in the Registry tree. Specify the new larger value in milliseconds. For example, the value 120000 tells Windows NT to wait up to 120 seconds.

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see Section 2.3.11, "Starting MySQL from the Windows Command Line".

Please see Section 2.3.14, "Troubleshooting a MySQL Installation Under Windows" if you encounter difficulties during installation.

2.3.13. Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> C:\mysql\bin\mysqlshow
C:\> C:\mysql\bin\mysqlshow -u root mysql
C:\> C:\mysql\bin\mysqladmin version status proc
C:\> C:\mysql\bin\mysql test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs on Windows 9x/Me, there is probably a problem with your DNS. In this case, start `mysqld` with the --

-skip-name-resolve option and use only `localhost` and IP numbers in the `Host` column of the MySQL grant tables.

You can force a MySQL client to use a named pipe connection rather than TCP/IP by specifying the `--pipe` option or by specifying . (period) as the host name. Use the `--socket` option to specify the name of the pipe. As of MySQL 4.1, you can use the `--protocol=PIPE` option instead.

There are two versions of the MySQL command-line tool on Windows:

Binary	Description
`mysql`	Compiled on native Windows, offering limited text editing capabilities.
`mysqlc`	Compiled with the Cygnus GNU compiler and libraries, which offers `readline` editing. `mysqlc` was intended for use primarily with Windows 9x/Me. It does not support the updated authentication protocol used beginning with MySQL 4.1, and is not supported in MySQL 4.1 and above. Beginning with MySQL 4.1.8, it is no longer included in MySQL Windows distributions.

To use `mysqlc`, you must have a copy of the `cygwinb19.dll` library installed somewhere that `mysqlc` can find it. If your distribution does not have the `cygwinb19.dll` library in the `bin` directory under the base directory of your MySQL installation, look for it in the `lib` directory and copy it to your Windows system directory (`\Windows\system` or a similar place).

2.3.14. Troubleshooting a MySQL Installation Under Windows

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. The purpose of this section is to help you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the error log. The MySQL server uses the error log to record information relevant to the error that is preventing the server from starting. The error log is located in the data directory specified in your `my.ini` file. The default data directory location is `C:\mysql\data`. See Section 5.10.1, "The Error Log".

Another source of information regarding possible errors is the console messages displayed when the MySQL service is starting. Use the `NET START mysql` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See Section 2.3.12, "Starting MySQL as a Windows Service".

The following are examples of some of the more common error messages you may encounter when installing MySQL and starting the server for the first time:

*
```
System error 1067 has occurred.
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

These messages occur when the MySQL server cannot find the `mysql` privileges database or other critical files. This error is often encountered when the MySQL base or data directories are installed in different locations than the default locations (`C:\mysql` and `C:\mysql\data`, respectively).

One situation when this may occur is when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new install location. In addition there may be old and new configuration files that conflict, be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\mysql` you need to ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. The `my.ini` file needs to be located in your Windows directory, typically located at `C:\WinNT` or

`C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable by issuing the following command from the command prompt:

```
C:\> echo %WINDIR%
```

An option file can be created and modified with any text editor, such as the Notepad program. For example, if MySQL is installed at `E:\mysql` and the data directory is located at `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the basedir and datadir parameters:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Note that Windows pathnames are specified in option files using forward slashes rather than backslashes. If you do use backslashes, you must double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\mysql
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See Section 2.3.8, "Creating an Option File".

-
  ```
  Error: Cannot create Windows service for MySql. Error: 0
  ```

  This error is encountered when you re-install or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Configuration Wizard. This happens because when the Configuration Wizard tries to install the service it finds an existing service with the same name.

  One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This will allow the new service to be installed correctly, but leaves the outdated service in place. While this is harmless it is best to remove old services that are no longer in use.

  To permanently remove the old mysql service, execute the following command as a user with administrative privileges, on the command-line:

  ```
  C:\>sc delete mysql
  [SC] DeleteService SUCCESS
  ```

  If the `sc` utility is not available for your version of Windows, download the `delsrv` utility from http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp and use the `delsrv mysql` syntax.

2.3.15. Upgrading MySQL on Windows

This section lists some of the steps you should take when upgrading MySQL on Windows.

1. You should always back up your current MySQL installation before performing an upgrade.

See Section 5.8.1, "Database Backups".

2. Download the latest Windows distribution of MySQL from http://dev.mysql.com.

3. Before upgrading MySQL, you must stop the server.

   If the server is installed as a service, stop the service with the following command from the command prompt:

   ```
   C:\> NET STOP MySQL
   ```

   If you are not running the MySQL server as a service, use the following command to stop the server:

   ```
   C:\> C:\mysql\bin\mysqladmin -u root shutdown
   ```

4. When upgrading to MySQL 4.1.5 or higher from a previous version, or when upgrading from a version of MySQL installed from a Zip archive to a version of MySQL installed with the MySQL Installation Wizard, you must manually remove the previous installation and MySQL service (if the server is installed as a service).

   To remove the MySQL service, use the following command:

   ```
   C:\> C:\mysql\bin\mysqld --remove
   ```

   If you do not remove the existing service, the MySQL Installation Wizard may fail to properly install the new MySQL service.

5. If you are using the MySQL Installation Wizard, start the wizard as described in Section 2.3.4, "Using the MySQL Installation Wizard".

6. If you are installing MySQL from a Zip archive, extract the archive. You may either overwrite your existing MySQL installation (usually located at C:\mysql), or install it into a different directory, such as C:\mysql4. Overwriting the existing installation is recommended.

7. Restart the server. For example, use NET START MySQL if you run MySQL as a service, or invoke mysqld directly otherwise.

8. Refer to Section 2.10, "Upgrading MySQL" for additional information on upgrading MySQL that is not specific to Windows.

9. If you encounter errors, see Section 2.3.14, "Troubleshooting a MySQL Installation Under Windows".

2.3.16. MySQL on Windows Compared to MySQL on Unix

MySQL for Windows has proven itself to be very stable. The Windows version of MySQL has the same features as the corresponding Unix version, with the following exceptions:

- **Windows 95 and threads**

  Windows 95 leaks about 200 bytes of main memory for each thread creation. Each connection in MySQL creates a new thread, so you shouldn't run mysqld for an extended time on Windows 95 if your server handles many connections! Other versions of Windows don't suffer from this bug.

- **Limited number of ports**

Windows systems have about 4,000 ports available for client connections, and after a connection on a port closes, it takes two to four minutes before the port can be reused. In situations where clients connect to and disconnect from the server at a high rate, it is possible for all available ports to be used up before closed ports become available again. If this happens, the MySQL server appears to be unresponsive even though it is running. Note that ports may be used by other applications running on the machine as well, in which case the number of ports available to MySQL is lower.

For more information, see http://support.microsoft.com/default.aspx?scid=kb;en-us;196271.

- **Concurrent reads**

  MySQL depends on the `pread()` and `pwrite()` calls to be able to mix `INSERT` and `SELECT`. Currently we use mutexes to emulate `pread()`/`pwrite()`. We will, in the long run, replace the file level interface with a virtual interface so that we can use the `readfile()`/`writefile()` interface on NT, 2000, and XP to get more speed. The current implementation limits the number of open files MySQL can use to 2,048 (1,024 before MySQL 4.0.19), which means that you cannot run as many concurrent threads on NT, 2000, XP, and 2003 as on Unix.

- **Blocking read**

  MySQL uses a blocking read for each connection, which has the following implications if named pipe connections are enabled:

  - A connection is not disconnected automatically after eight hours, as happens with the Unix version of MySQL.

  - If a connection hangs, it's impossible to break it without killing MySQL.

  - `mysqladmin kill` does not work on a sleeping connection.

  - `mysqladmin shutdown` can't abort as long as there are sleeping connections.

  We plan to fix this problem when our Windows developers have figured out a nice workaround.

- **ALTER TABLE**

  While you are executing an `ALTER TABLE` statement, the table is locked from being used by other threads. This has to do with the fact that on Windows, you can't delete a file that is in use by another thread. In the future, we may find some way to work around this problem.

- **DROP TABLE**

  `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` handler does the table mapping hidden from the upper layer of MySQL. Because Windows doesn't allow you to drop files that are open, you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table. We will fix this at the same time we introduce views.

- **DATA DIRECTORY and INDEX DIRECTORY**

  The `DATA DIRECTORY` and `INDEX DIRECTORY` options for `CREATE TABLE` are ignored on Windows, because Windows doesn't support symbolic links. These options also are ignored on systems that have a non-functional `realpath()` call.

- **DROP DATABASE**

  You cannot drop a database that is in use by some thread.

- **Killing MySQL from the Task Manager**

  You cannot kill MySQL from the Task Manager or with the shutdown utility in Windows 95.

You must stop it with `mysqladmin shutdown`.

- **Case-insensitive names**

  Filenames are not case sensitive on Windows, so MySQL database and table names are also not case sensitive on Windows. The only restriction is that database and table names must be specified using the same case throughout a given statement. See Section 9.2.2, "Identifier Case Sensitivity".

- **The '\' pathname separator character**

  Pathname components in Windows are separated by the '\' character, which is also the escape character in MySQL. If you are using `LOAD DATA INFILE` or `SELECT ... INTO OUT-FILE`, use Unix-style filenames with '/' characters:

  ```
  mysql> LOAD DATA INFILE 'C:/tmp/skr.txt' INTO TABLE skr;
  mysql> SELECT * INTO OUTFILE 'C:/tmp/skr.txt' FROM skr;
  ```

  Alternatively, you must double the '\' character:

  ```
  mysql> LOAD DATA INFILE 'C:\\tmp\\skr.txt' INTO TABLE skr;
  mysql> SELECT * INTO OUTFILE 'C:\\tmp\\skr.txt' FROM skr;
  ```

- **Problems with pipes.**

  Pipes do not work reliably from the Windows command-line prompt. If the pipe includes the character `^Z` / `CHAR(24)`, Windows thinks it has encountered end-of-file and aborts the program.

  This is mainly a problem when you try to apply a binary log as follows:

  ```
  C:\> mysqlbinlog binary-log-name | mysql --user=root
  ```

  If you have a problem applying the log and suspect that it is because of a `^Z` / `CHAR(24)` character, you can use the following workaround:

  ```
  C:\> mysqlbinlog binary-log-file --result-file=/tmp/bin.sql
  C:\> mysql --user=root --execute "source /tmp/bin.sql"
  ```

  The latter command also can be used to reliably read in any SQL file that may contain binary data.

- **`Access denied for user` error**

  If you attempt to run a MySQL client program to connect to a server running on the same machine, but get the error `Access denied for user 'some-user'@'unknown' to database 'mysql'`, this means that MySQL cannot resolve your hostname properly.

  To fix this, you should create a file named `\windows\hosts` containing the following information:

  ```
  127.0.0.1       localhost
  ```

Here are some open issues for anyone who might want to help us improve MySQL on Windows:

- Add macros to use the faster thread-safe increment/decrement methods provided by Windows.

2.4. Installing MySQL on Linux

The recommended way to install MySQL on Linux is by using the RPM packages. The MySQL RPMs are currently built on a SuSE Linux 7.3 system, but should work on most versions of Linux that support `rpm` and use `glibc`. To obtain RPM packages, see Section 2.1.3, "How to Get MySQL".

MySQL AB does provide some platform-specific RPMs; the difference between a platform-specific RPM and a generic RPM is that the platform-specific RPMs are built on the targeted platform and are linked dynamically whereas the generic RPM is linked statically with LinuxThreads.

Note: RPM distributions of MySQL often are provided by other vendors. Be aware that they may differ in features and capabilities from those built by MySQL AB, and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

If you have problems with an RPM file (for example, if you receive the error "`Sorry, the host 'xxxx' could not be looked up`"), see Section 2.12.1.2, "Linux Binary Distribution Notes".

In most cases, you only need to install the `MySQL-server` and `MySQL-client` packages to get a functional MySQL installation. The other packages are not required for a standard installation. If you want to run a MySQL-Max server that has additional capabilities, you should also install the `MySQL-Max` RPM. However, you should do so only *after* installing the `MySQL-server` RPM. See Section 5.1.2, "The `mysqld-max` Extended MySQL Server".

If you get a dependency failure when trying to install the MySQL 4.0 packages (for example, "`error: removing these packages would break dependencies: libmysqlclient.so.10 is needed by ...`"), you should also install the package `MySQL-shared-compat`, which includes both the shared libraries for backward compatibility (`libmysqlclient.so.12` for MySQL 4.0 and `libmysqlclient.so.10` for MySQL 3.23).

Many Linux distributions still ship with MySQL 3.23 and they usually link applications dynamically to save disk space. If these shared libraries are in a separate package (for example, `MySQL-shared`), it is sufficient to simply leave this package installed and just upgrade the MySQL server and client packages (which are statically linked and do not depend on the shared libraries). For distributions that include the shared libraries in the same package as the MySQL server (for example, Red Hat Linux), you could either install our 3.23 `MySQL-shared` RPM, or use the `MySQL-shared-compat` package instead.

The following RPM packages are available:

- `MySQL-server-VERSION.i386.rpm`

  The MySQL server. You need this unless you only want to connect to a MySQL server running on another machine. Note: Server RPM files were called `MySQL-VERSION.i386.rpm` before MySQL 4.0.10. That is, they did not have `-server` in the name.

- `MySQL-Max-VERSION.i386.rpm`

  The MySQL-Max server. This server has additional capabilities that the one provided in the `MySQL-server` RPM does not. You must install the `MySQL-server` RPM first, because the `MySQL-Max` RPM depends on it.

- `MySQL-client-VERSION.i386.rpm`

  The standard MySQL client programs. You probably always want to install this package.

- `MySQL-bench-VERSION.i386.rpm`

  Tests and benchmarks. Requires Perl and the `DBD::mysql` module.

- `MySQL-devel-VERSION.i386.rpm`

  The libraries and include files that are needed if you want to compile other MySQL clients, such as the Perl modules.

- `MySQL-shared-VERSION.i386.rpm`

  This package contains the shared libraries (`libmysqlclient.so*`) that certain languages and applications need to dynamically load and use MySQL.

- `MySQL-shared-compat-VERSION.i386.rpm`

  This package includes the shared libraries for both MySQL 3.23 and MySQL 4.0. Install this package instead of `MySQL-shared` if you have applications installed that are dynamically linked against MySQL 3.23 but you want to upgrade to MySQL 4.0 without breaking the library dependencies. This package has been available since MySQL 4.0.13.

- `MySQL-embedded-VERSION.i386.rpm`

  The embedded MySQL server library (from MySQL 4.0).

- `MySQL-VERSION.src.rpm`

  This contains the source code for all of the previous packages. It can also be used to rebuild the RPMs on other architectures (for example, Alpha or SPARC).

To see all files in an RPM package (for example, a `MySQL-server` RPM), run:

```
shell> rpm -qpl MySQL-server-VERSION.i386.rpm
```

To perform a standard minimal installation, run:

```
shell> rpm -i MySQL-server-VERSION.i386.rpm
shell> rpm -i MySQL-client-VERSION.i386.rpm
```

To install just the client package, run:

```
shell> rpm -i MySQL-client-VERSION.i386.rpm
```

RPM provides a feature to verify the integrity and authenticity of packages before installing them. If you would like to learn more about this feature, see Section 2.1.4, "Verifying Package Integrity Using MD5 Checksums or `GnuPG`".

The server RPM places data under the `/var/lib/mysql` directory. The RPM also creates a login account for a user named `mysql` (if one does not exist) to use for running the MySQL server, and creates the appropriate entries in `/etc/init.d/` to start the server automatically at boot time. (This means that if you have performed a previous installation and have made changes to its startup script, you may want to make a copy of the script so that you don't lose it when you install a newer RPM.) See Section 2.9.2.2, "Starting and Stopping MySQL Automatically" for more information on how MySQL can be started automatically on system startup.

If you want to install the MySQL RPM on older Linux distributions that do not support initialization scripts in `/etc/init.d` (directly or via a symlink), you should create a symbolic link that points to the location where your initialization scripts actually are installed. For example, if that location is `/etc/rc.d/init.d`, use these commands before installing the RPM to create `/etc/init.d` as a symbolic link that points there:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

However, all current major Linux distributions should support the new directory layout that uses `/etc/init.d`, because it is required for LSB (Linux Standard Base) compliance.

If the RPM files that you install include `MySQL-server`, the `mysqld` server should be up and running after installation. You should be able to start using MySQL.

If something goes wrong, you can find more information in the binary installation section. See Section 2.7, "Installing MySQL on Other Unix-Like Systems".

Note: The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.9, "Post-Installation Setup and Testing".

2.5. Installing MySQL on Mac OS X

Beginning with MySQL 4.0.11, you can install MySQL on Mac OS X 10.2.x ("Jaguar") and up using a Mac OS X binary package in PKG format instead of the binary tarball distribution. Please note that older versions of Mac OS X (for example, 10.1.x) are not supported by this package.

The package is located inside a disk image (`.dmg`) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

To obtain MySQL, see Section 2.1.3, "How to Get MySQL".

Note: Before proceeding with the installation, be sure to shut down all running MySQL server instances by either using the MySQL Manager Application (on Mac OS X Server) or via `mysqladmin shutdown` on the command line.

To actually install the MySQL PKG file, double-click on the package icon. This launches the Mac OS X Package Installer, which guides you through the installation of MySQL.

Due to a bug in the Mac OS X package installer, you may see this error message in the destination disk selection dialog:

```
You cannot install this software on this disk. (null)
```

If this error occurs, simply click the `Go Back` button once to return to the previous screen. Then click `Continue` to advance to the destination disk selection again, and you should be able to choose the destination disk correctly. We have reported this bug to Apple and it is investigating this problem.

The Mac OS X PKG of MySQL installs itself into `/usr/local/mysql-VERSION` and also installs a symbolic link, `/usr/local/mysql`, pointing to the new location. If a directory named `/usr/local/mysql` exists, it is renamed to `/usr/local/mysql.bak` first. Additionally, the installer creates the grant tables in the `mysql` database by executing `mysql_install_db` after the installation.

The installation layout is similar to that of a `tar` file binary distribution; all MySQL binaries are located in the directory `/usr/local/mysql/bin`. The MySQL socket file is created as `/tmp/mysql.sock` by default. See Section 2.1.5, "Installation Layouts".

MySQL installation requires a Mac OS X user account named `mysql`. A user account with this name should exist by default on Mac OS X 10.2 and up.

If you are running Mac OS X Server, you have a version of MySQL installed. The versions of MySQL that ship with Mac OS X Server versions are shown in the following table:

Mac OS X Server Version	MySQL Version
10.2-10.2.2	3.23.51
10.2.3-10.2.6	3.23.53

10.3	4.0.14
10.3.2	4.0.16
10.4.0	4.1.10a

This manual section covers the installation of the official MySQL Mac OS X PKG only. Make sure to read Apple's help information about installing MySQL: Run the "Help View" application, select "Mac OS X Server" help, do a search for "MySQL," and read the item entitled "Installing MySQL."

For pre-installed versions of MySQL on Mac OS X Server, note especially that you should start `mysqld` with `safe_mysqld` instead of `mysqld_safe` if MySQL is older than version 4.0.

If you previously used Marc Liyanage's MySQL packages for Mac OS X from ht-tp://www.entropy.ch, you can simply follow the update instructions for packages using the binary installation layout as given on his pages.

If you are upgrading from Marc's 3.23.xx versions or from the Mac OS X Server version of MySQL to the official MySQL PKG, you also need to convert the existing MySQL privilege tables to the current format, because some new security privileges have been added. See Section 2.10.8, "Upgrading the Grant Tables".

If you would like to automatically start up MySQL during system startup, you also need to install the MySQL Startup Item. Starting with MySQL 4.0.15, it is part of the Mac OS X installation disk images as a separate installation package. Simply double-click the `MySQLStartupItem.pkg` icon and follow the instructions to install it.

Note that the Startup Item need be installed only once! There is no need to install it each time you upgrade the MySQL package later.

The Startup Item is installed into `/Library/StartupItems/MySQLCOM`. (Before MySQL 4.1.2, the location was `/Library/StartupItems/MySQL`, but that collided with the MySQL Startup Item installed by Mac OS X Server.) Startup Item installation adds a variable `MYSQL-COM=-YES-` to the system configuration file `/etc/hostconfig`. If you would like to disable the automatic startup of MySQL, simply change this variable to `MYSQLCOM=-NO-`.

On Mac OS X Server, the default MySQL installation uses the variable `MYSQL` in the `/etc/hostconfig` file. The MySQL AB Startup Item installer disables this variable by setting it to `MYSQL=-NO-`. This avoids boot time conflicts with the `MYSQLCOM` variable used by the MySQL AB Startup Item. However, it does not shut down a running MySQL server. You should do that yourself.

After the installation, you can start up MySQL by running the following commands in a terminal window. You must have administrator privileges to perform this task.

If you have installed the Startup Item:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM start
(Enter your password, if necessary)
(Press Control-D or enter "exit" to exit the shell)
```

For versions of MySQL older than 4.1.3, substitute `/Library/StartupItems/MySQLCOM/MySQLCOM` with `/Library/StartupItems/MySQL/MySQL` above.

If you don't use the Startup Item, enter the following command sequence:

```
shell> cd /usr/local/mysql
shell> sudo ./bin/mysqld_safe
(Enter your password, if necessary)
(Press Control-Z)
shell> bg
(Press Control-D or enter "exit" to exit the shell)
```

You should be able to connect to the MySQL server, for example, by running `/usr/local/mysql/bin/mysql`.

Note: The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.9, "Post-Installation Setup and Testing".

You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `tcsh` is:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

For `bash`, use:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. For example, add the following line to your `$HOME/.tcshrc` file if your shell is `tcsh`:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If no `.tcshrc` file exists in your home directory, create it with a text editor.

If you are upgrading an existing installation, please note that installing a new MySQL PKG does not remove the directory of an older installation. Unfortunately, the Mac OS X Installer does not yet offer the functionality required to properly upgrade previously installed packages.

To use your existing databases with the new installation, you'll need to copy the contents of the old data directory to the new data directory. Make sure that neither the old server nor the new one is running when you do this. After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

2.6. Installing MySQL on NetWare

Porting MySQL to NetWare was an effort spearheaded by Novell. Novell customers should be pleased to note that NetWare 6.5 ships with bundled MySQL binaries, complete with an automatic commercial use license for all servers running that version of NetWare.

MySQL for NetWare is compiled using a combination of `Metrowerks CodeWarrior for NetWare` and special cross-compilation versions of the GNU autotools.

The latest binary packages for NetWare can be obtained at http://dev.mysql.com/downloads/. See Section 2.1.3, "How to Get MySQL".

In order to host MySQL, the NetWare server must meet these requirements:

• Latest Support Pack of NetWare 6.5 [http://support.novell.com/filefinder/18197/index.html] or NetWare 6.0 [http://support.novell.com/filefinder/13659/index.html] installed.

• The system must meet Novell's minimum requirements to run the respective version of NetWare.

• MySQL data, as well as the binaries themselves, must be installed on an NSS volume; traditional volumes are not supported.

To install MySQL for NetWare, use the following procedure:

1. If you are upgrading from a prior installation, stop the MySQL server. This is done from the server console, using the following command:

   ```
   SERVER:  mysqladmin -u root shutdown
   ```

2. Log on to the target server from a client machine with access to the location where you are installing MySQL.

3. Extract the binary package Zip file onto the server. Be sure to allow the paths in the Zip file to be used. It is safe to simply extract the file to `SYS:\`.

   If you are upgrading from a prior installation, you may need to copy the data directory (for example, `SYS:MYSQL\DATA`), as well as `my.cnf`, if you have customized it. You can then delete the old copy of MySQL.

4. You might want to rename the directory to something more consistent and easy to use. The examples iin this manual use `SYS:MYSQL` to refer to the installation directory.

   Note that MySQL installation on NetWare does not detect if a version of MySQL is already installed outside the NetWare release. Therefore, if you have installed the latest MySQL version from the Web (for example, MySQL 4.1 or later) in `SYS:\MYSQL`, you must rename the folder before upgrading the NetWare server; otherwise, files in `SYS:\MySQL` are overwritten by the MySQL version present in NetWare Support Pack.

5. At the server console, add a search path for the directory containing the MySQL NLMs. For example:

   ```
   SERVER:  SEARCH ADD SYS:MYSQL\BIN
   ```

6. Initialize the data directory and the grant tables, if needed, by executing `mysql_install_db` at the server console.

7. Start the MySQL server using `mysqld_safe` at the server console.

8. To finish the installation, you should also add the following commands to `autoexec.ncf`. For example, if your MySQL installation is in `SYS:MYSQL` and you want MySQL to start automatically, you could add these lines:

   ```
   #Starts the MySQL 4.0.x database server
   SEARCH ADD SYS:MYSQL\BIN
   MYSQLD_SAFE
   ```

   If you are running MySQL on NetWare 6.0, we strongly suggest that you use the `--skip-external-locking` option on the command line:

   ```
   #Starts the MySQL 4.0.x database server
   SEARCH ADD SYS:MYSQL\BIN
   MYSQLD_SAFE --skip-external-locking
   ```

   It is also necessary to use `CHECK TABLE` and `REPAIR TABLE` instead of `myisamchk`, because `myisamchk` makes use of external locking. External locking is known to have problems on NetWare 6.0; the problem has been eliminated in NetWare 6.5.

   `mysqld_safe` on NetWare provides a screen presence. When you unload (shut down) the `mysqld_safe` NLM, the screen does not by default go away. Instead, it prompts for user input:

   ```
   *<NLM has terminated; Press any key to close the screen>*
   ```

If you want NetWare to close the screen automatically instead, use the `--autoclose` option to `mysqld_safe`. For example:

```
#Starts the MySQL 4.0.x database server
SEARCH ADD SYS:MYSQL\BIN
MYSQLD_SAFE --autoclose
```

9. When installing MySQL version 4.1.x or later either for the first time or upgrading the 4.0.x version to 4.1.x or later, download and install the latest and appropriate Perl module and PHP extension:

   • Perl for NetWare: http://forge.novell.com/modules/xfcontent/downloads.php/perl/Modules/

   • PHP for NetWare: http://forge.novell.com/modules/xfcontent/downloads.php/php/Modules/

The behavior of `mysqld_safe` on NetWare is described further in Section 5.1.3, "mysqld_safe — MySQL Server Startup Script".

If there was an existing installation of MySQL on the server, be sure to check for existing MySQL startup commands in `autoexec.ncf`, and edit or delete them as necessary.

Note: The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.9, "Post-Installation Setup and Testing".

2.7. Installing MySQL on Other Unix-Like Systems

This section covers the installation of MySQL binary distributions that are provided for various platforms in the form of compressed `tar` files (files with a `.tar.gz` extension). See Section 2.1.2.5, "MySQL Binaries Compiled by MySQL AB" for a detailed list.

To obtain MySQL, see Section 2.1.3, "How to Get MySQL".

MySQL `tar` file binary distributions have names of the form `mysql-VERSION-OS.tar.gz`, where *VERSION* is a number (for example, `4.0.17`), and *OS* indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686`).

In addition to these generic packages, we also offer binaries in platform-specific package formats for selected platforms. See Section 2.2, "Standard MySQL Installation Using a Binary Distribution" for more information on how to install these.

You need the following tools to install a MySQL `tar` file binary distribution:

• GNU `gunzip` to uncompress the distribution.

• A reasonable `tar` to unpack the distribution. GNU `tar` is known to work. Some operating systems come with a pre-installed version of `tar` that is known to have problems. For example, Mac OS X `tar` and Sun `tar` are known to have problems with long filenames. On Mac OS X, you can use the pre-installed `gnutar` program. On other systems with a deficient `tar`, you should install GNU `tar` first.

If you run into problems, *please always use `mysqlbug`* when posting questions to a MySQL mailing list. Even if the problem isn't a bug, `mysqlbug` gathers system information that helps others solve your problem. By not using `mysqlbug`, you lessen the likelihood of getting a solution to your

problem. You can find `mysqlbug` in the `bin` directory after you unpack the distribution. See Section 1.7.1.3, "How to Report Bugs or Problems".

The basic commands you must execute to install and use a MySQL binary distribution are:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
shell> cd /usr/local
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root    .
shell> chown -R mysql data
shell> chgrp -R mysql .
shell> bin/mysqld_safe --user=mysql &
```

For versions of MySQL older than 4.0, substitute `bin/safe_mysqld` for `bin/mysqld_safe` in the final command.

Note: This procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.9, "Post-Installation Setup and Testing".

A more detailed version of the preceding description for installing a binary distribution follows:

1. Add a login user and group for `mysqld` to run as:

    ```
    shell> groupadd mysql
    shell> useradd -g mysql mysql
    ```

    These commands add the `mysql` group and the `mysql` user. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix. They may also be called `adduser` and `addgroup`.

    You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following steps.

2. Pick the directory under which you want to unpack the distribution, and change location into it. In the following example, we unpack the distribution under `/usr/local`. (The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you need to perform the installation as `root`.)

    ```
    shell> cd /usr/local
    ```

3. Obtain a distribution file from one of the sites listed in Section 2.1.3, "How to Get MySQL". For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

4. Unpack the distribution, which creates the installation directory. Then create a symbolic link to that directory:

    ```
    shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
    shell> ln -s full-path-to-mysql-VERSION-OS mysql
    ```

    The `tar` command creates a directory named `mysql-VERSION-OS`. The `ln` command makes a symbolic link to that directory. This lets you refer more easily to the installation directory as `/usr/local/mysql`.

    With GNU `tar`, no separate invocation of `gunzip` is necessary. You can replace the first line with the following alternative command to uncompress and extract the distribution:

    ```
    shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
    ```

5. Change location into the installation directory:

```
shell> cd mysql
```

You can find several files and subdirectories in the `mysql` directory. The most important for installation purposes are the `bin` and `scripts` subdirectories.

- `bin`

  This directory contains client programs and the server. You should add the full pathname of this directory to your `PATH` environment variable so that your shell finds the MySQL programs properly. See Appendix G, *Environment Variables*.

- `scripts`

  This directory contains the `mysql_install_db` script used to initialize the `mysql` database containing the grant tables that store the server access permissions.

6. If you haven't installed MySQL before, you must create the MySQL grant tables:

```
shell> scripts/mysql_install_db --user=mysql
```

If you run the command as `root`, you should use the `--user` option as shown. The value of the option should be the name of the login account that you created in the first step to use for running the server. If you run the command while logged in as that user, you can omit the `--user` option.

Note that for MySQL versions older than 3.22.10, `mysql_install_db` left the server running after creating the grant tables. This is no longer true; you need to restart the server after performing the remaining steps in this procedure.

7. Change the ownership of program binaries to `root` and ownership of the data directory to the user that you run `mysqld` as. Assuming that you are located in the installation directory (`/usr/local/mysql`), the commands look like this:

```
shell> chown -R root  .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

The first command changes the owner attribute of the files to the `root` user. The second changes the owner attribute of the data directory to the `mysql` user. The third changes the group attribute to the `mysql` group.

8. If you would like MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `support-files/mysql.server` script itself and in Section 2.9.2.2, "Starting and Stopping MySQL Automatically".

9. You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD::mysql` Perl modules. For instructions, see Section 2.13, "Perl Installation Notes".

10. If you would like to use `mysqlaccess` and have the MySQL distribution in some non-standard place, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `bin/mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL     = '/usr/local/bin/mysql';    # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, you get a `Broken pipe` error when you run `mysqlaccess`.

After everything has been unpacked and installed, you should test your distribution.

You can start the MySQL server with the following command:

```
shell> bin/mysqld_safe --user=mysql &
```

For versions of MySQL older than 4.0, substitute `bin/safe_mysqld` for `bin/mysqld_safe` in the command.

More information about `mysqld_safe` is given in Section 5.1.3, "mysqld_safe — MySQL Server Startup Script".

Note: The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.9, "Post-Installation Setup and Testing".

2.8. MySQL Installation Using a Source Distribution

Before you proceed with the source installation, check first to see whether our binary is available for your platform and whether it works for you. We put a lot of effort into making sure that our binaries are built with the best possible options.

To obtain a source distribution for MySQL, Section 2.1.3, "How to Get MySQL".

MySQL source distributions are provided as compressed `tar` archives and have names of the form `mysql-VERSION.tar.gz`, where `VERSION` is a number like `5.0.6-beta`.

You need the following tools to build and install MySQL from source:

- GNU `gunzip` to uncompress the distribution.

- A reasonable `tar` to unpack the distribution. GNU `tar` is known to work. Some operating systems come with a pre-installed version of `tar` that is known to have problems. For example, Mac OS X `tar` and Sun `tar` are known to have problems with long filenames. On Mac OS X, you can use the pre-installed `gnutar` program. On other systems with a deficient `tar`, you should install GNU `tar` first.

- A working ANSI C++ compiler. `gcc` 2.95.2 or later, `egcs` 1.0.2 or later or `egcs` `2.91.66`, SGI C++, and SunPro C++ are some of the compilers that are known to work. `libg++` is not needed when using `gcc`. `gcc` 2.7.x has a bug that makes it impossible to compile some perfectly legal C++ files, such as `sql/sql_base.cc`. If you have only `gcc` 2.7.x, you must upgrade your `gcc` to be able to compile MySQL. `gcc` 2.8.1 is also known to have problems on some platforms, so it should be avoided if a new compiler exists for the platform.

  `gcc` 2.95.2 or later is recommended when compiling MySQL 3.23.x.

- A good `make` program. GNU `make` is always recommended and is sometimes required. If you have problems, we recommend trying GNU `make` 3.75 or newer.

If you are using a version of `gcc` recent enough to understand the `-fno-exceptions` option, it is *very important* that you use this option. Otherwise, you may compile a binary that crashes randomly. We also recommend that you use `-felide-constructors` and `-fno-rtti` along with `-fno-exceptions`. When in doubt, do the following:

```
CFLAGS="-O3" CXX=gcc CXXFLAGS="-O3 -felide-constructors \
        -fno-exceptions -fno-rtti" ./configure \
        --prefix=/usr/local/mysql --enable-assembler \
        --with-mysqld-ldflags=-all-static
```

On most systems, this gives you a fast and stable binary.

If you run into problems, *please always use `mysqlbug`* when posting questions to a MySQL mailing list. Even if the problem isn't a bug, `mysqlbug` gathers system information that helps others solve your problem. By not using `mysqlbug`, you lessen the likelihood of getting a solution to your problem. You can find `mysqlbug` in the `scripts` directory after you unpack the distribution. See Section 1.7.1.3, "How to Report Bugs or Problems".

2.8.1. Source Installation Overview

The basic commands you must execute to install a MySQL source distribution are:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
shell> gunzip < mysql-VERSION.tar.gz | tar -xvf -
shell> cd mysql-VERSION
shell> ./configure --prefix=/usr/local/mysql
shell> make
shell> make install
shell> cp support-files/my-medium.cnf /etc/my.cnf
shell> cd /usr/local/mysql
shell> bin/mysql_install_db --user=mysql
shell> chown -R root  .
shell> chown -R mysql var
shell> chgrp -R mysql .
shell> bin/mysqld_safe --user=mysql &
```

For versions of MySQL older than 4.0, substitute `bin/safe_mysqld` for `bin/mysqld_safe` in the final command.

If you start from a source RPM, do the following:

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

This makes a binary RPM that you can install. For older versions of RPM, you may have to replace the command `rpmbuild` with `rpm` instead.

Note: This procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.9, "Post-Installation Setup and Testing", for post-installation setup and testing.

A more detailed version of the preceding description for installing MySQL from a source distribution follows:

1. Add a login user and group for `mysqld` to run as:

    ```
    shell> groupadd mysql
    shell> useradd -g mysql mysql
    ```

    These commands add the `mysql` group and the `mysql` user. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix. They may also be called `adduser` and `addgroup`.

    You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following steps.

2. Pick the directory under which you want to unpack the distribution, and change location into it.

3. Obtain a distribution file from one of the sites listed in Section 2.1.3, "How to Get MySQL".

4. Unpack the distribution into the current directory:

```
shell> gunzip < /path/to/mysql-VERSION.tar.gz | tar xvf -
```

This command creates a directory named mysql-VERSION.

With GNU tar, no separate invocation of gunzip is necessary. You can use the following alternative command to uncompress and extract the distribution:

```
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
```

5. Change location into the top-level directory of the unpacked distribution:

```
shell> cd mysql-VERSION
```

Note that currently you must configure and build MySQL from this top-level directory. You cannot build it in a different directory.

6. Configure the release and compile everything:

```
shell> ./configure --prefix=/usr/local/mysql
shell> make
```

When you run configure, you might want to specify some options. Run ./configure --help for a list of options. Section 2.8.2, "Typical configure Options", discusses some of the more useful options.

If configure fails and you are going to send mail to a MySQL mailing list to ask for assistance, please include any lines from config.log that you think can help solve the problem. Also include the last couple of lines of output from configure. Post the bug report using the mysqlbug script. See Section 1.7.1.3, "How to Report Bugs or Problems".

If the compile fails, see Section 2.8.4, "Dealing with Problems Compiling MySQL" for help.

7. Install the distribution:

```
shell> make install
```

If you want to set up an option file, use one of those present in the support-files directory as a template. For example:

```
shell> cp support-files/my-medium.cnf /etc/my.cnf
```

You might need to run these commands as root.

If you want to configure support for InnoDB tables, you should edit the /etc/my.cnf file, remove the # character before the option lines that start with innodb_..., and modify the option values to be what you want. See Section 4.3.2, "Using Option Files" and Section 15.4, "InnoDB Configuration".

8. Change location into the installation directory:

```
shell> cd /usr/local/mysql
```

9. If you haven't installed MySQL before, you must create the MySQL grant tables:

```
shell> bin/mysql_install_db --user=mysql
```

If you run the command as `root`, you should use the `--user` option as shown. The value of the option should be the name of the login account that you created in the first step to use for running the server. If you run the command while logged in as that user, you can omit the `--user` option.

Note that for MySQL versions older than 3.22.10, `mysql_install_db` left the server running after creating the grant tables. This is no longer true; you need to restart the server after performing the remaining steps in this procedure.

10. Change the ownership of program binaries to `root` and ownership of the data directory to the user that you run `mysqld` as. Assuming that you are located in the installation directory (`/usr/local/mysql`), the commands look like this:

```
shell> chown -R root  .
shell> chown -R mysql var
shell> chgrp -R mysql .
```

The first command changes the owner attribute of the files to the `root` user. The second changes the owner attribute of the data directory to the `mysql` user. The third changes the group attribute to the `mysql` group.

11. If you would like MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `support-files/mysql.server` script itself and in Section 2.9.2.2, "Starting and Stopping MySQL Automatically".

12. You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD::mysql` Perl modules. For instructions, see Section 2.13, "Perl Installation Notes".

After everything has been installed, you should initialize and test your distribution using this command:

```
shell> /usr/local/mysql/bin/mysqld_safe --user=mysql &
```

For versions of MySQL older than 4.0, substitute `safe_mysqld` for `mysqld_safe` in the command.

If that command fails immediately and prints `mysqld ended`, you can find some information in the *host_name*.err file in the data directory.

More information about `mysqld_safe` is given in Section 5.1.3, "mysqld_safe — MySQL Server Startup Script".

Note: The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.9, "Post-Installation Setup and Testing".

2.8.2. Typical `configure` Options

The `configure` script gives you a great deal of control over how you configure a MySQL source distribution. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. See Appendix G, *Environment Variables*. For a list of options supported by `configure`, run this command:

```
shell> ./configure --help
```

Some of the more commonly used `configure` options are described here:

- To compile just the MySQL client libraries and client programs and not the server, use the `--without-server` option:

```
shell> ./configure --without-server
```

If you don't have a C++ compiler, `mysql` cannot be compiled (it is the one client program that requires C++). In this case, you can remove the code in `configure` that tests for the C++ compiler and then run `./configure` with the `--without-server` option. The compile step should still try to build `mysql`, but you can ignore any warnings about `mysql.cc`. (If `make` stops, try `make -k` to tell it to continue with the rest of the build even if errors occur.)

- If you want to build the embedded MySQL library (`libmysqld.a`) you should use the `--with-embedded-server` option.

- If you don't want your log files and database directories located under `/usr/local/var`, use a `configure` command something like one of these:

```
shell> ./configure --prefix=/usr/local/mysql
shell> ./configure --prefix=/usr/local \
          --localstatedir=/usr/local/mysql/data
```

The first command changes the installation prefix so that everything is installed under `/usr/local/mysql` rather than the default of `/usr/local`. The second command preserves the default installation prefix, but overrides the default location for database directories (normally `/usr/local/var`) and changes it to `/usr/local/mysql/data`. After you have compiled MySQL, you can change these options with option files. See Section 4.3.2, "Using Option Files".

- If you are using Unix and you want the MySQL socket located somewhere other than the default location (normally in the directory `/tmp` or `/var/run`), use a `configure` command like this:

```
shell> ./configure \
          --with-unix-socket-path=/usr/local/mysql/tmp/mysql.sock
```

The socket filename must be an absolute pathname. You can also change the location of `mysql.sock` later by using a MySQL option file. See Section A.4.5, "How to Protect or Change the MySQL Socket File `/tmp/mysql.sock`".

- If you want to compile statically linked programs (for example, to make a binary distribution, to get more speed, or to work around problems with some Red Hat Linux distributions), run `configure` like this:

```
shell> ./configure --with-client-ldflags=-all-static \
          --with-mysqld-ldflags=-all-static
```

- If you are using `gcc` and don't have `libg++` or `libstdc++` installed, you can tell `configure` to use `gcc` as your C++ compiler:

```
shell> CC=gcc CXX=gcc ./configure
```

When you use `gcc` as your C++ compiler, it does not attempt to link in `libg++` or `libstdc++`. This may be a good idea to do even if you have these libraries installed, because some versions of them have caused strange problems for MySQL users in the past.

The following list indicates some compilers and environment variable settings that are commonly used with each one.

- `gcc` 2.7.2:

  ```
  CC=gcc CXX=gcc CXXFLAGS="-O3 -felide-constructors"
  ```

- `egcs` 1.0.3a:

  ```
  CC=gcc CXX=gcc CXXFLAGS="-O3 -felide-constructors \
  -fno-exceptions -fno-rtti"
  ```

- `gcc` 2.95.2:

  ```
  CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro \
  -felide-constructors -fno-exceptions -fno-rtti"
  ```

- `pgcc` 2.90.29 or newer:

  ```
  CFLAGS="-O3 -mpentiumpro -mstack-align-double" CXX=gcc \
  CXXFLAGS="-O3 -mpentiumpro -mstack-align-double \
  -felide-constructors -fno-exceptions -fno-rtti"
  ```

In most cases, you can get a reasonably optimized MySQL binary by using the options from the preceding list and adding the following options to the `configure` line:

```
--prefix=/usr/local/mysql --enable-assembler \
--with-mysqld-ldflags=-all-static
```

The full `configure` line would, in other words, be something like the following for all recent `gcc` versions:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro \
-felide-constructors -fno-exceptions -fno-rtti" ./configure \
--prefix=/usr/local/mysql --enable-assembler \
--with-mysqld-ldflags=-all-static
```

The binaries we provide on the MySQL Web site at http://www.mysql.com/ are all compiled with full optimization and should be perfect for most users. See Section 2.1.2.5, "MySQL Binaries Compiled by MySQL AB". There are some configuration settings you can tweak to make an even faster binary, but these are only for advanced users. See Section 7.5.4, "How Compiling and Linking Affects the Speed of MySQL".

If the build fails and produces errors about your compiler or linker not being able to create the shared library `libmysqlclient.so.N` (where *N* is a version number), you can work around this problem by giving the `--disable-shared` option to `configure`. In this case, `configure` does not build a shared `libmysqlclient.so.N` library.

-

  By default, MySQL uses the `latin1` (cp1252) character set. To change the default set, use the `--with-charset` option:

  ```
  shell> ./configure --with-charset=CHARSET
  ```

  CHARSET may be one of `big5`, `cp1251`, `cp1257`, `czech`, `danish`, `dec8`, `dos`, `euc_kr`, `gb2312`, `gbk`, `german1`, `hebrew`, `hp8`, `hungarian`, `koi8_ru`, `koi8_ukr`, `latin1`, `latin2`, `sjis`, `swe7`, `tis620`, `ujis`, `usa7`, or `win1251ukr`. See Section 5.9.1, "The Character Set Used for Data and Sorting".

  As of MySQL 4.1.1, the default collation may also be specified. MySQL uses the `latin1_swedish_ci` collation. To change this, use the `--with-collation` option:

```
shell> ./configure --with-collation=COLLATION
```

To change both the character set and the collation, use both the `--with-charset` and `--with-collation` options. The collation must be a legal collation for the character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.)

If you want to convert characters between the server and the client, you should take a look at the `SET CHARACTER SET` statement. See Section 13.5.3, "`SET` Syntax".

Warning: If you change character sets after having created any tables, you have to run `myis-amchk -r -q --set-character-set=charset` on every table. Your indexes may be sorted incorrectly otherwise. (This can happen if you install MySQL, create some tables, then reconfigure MySQL to use a different character set and reinstall it.)

With the `configure` option `--with-extra-charsets=LIST`, you can define which additional character sets should be compiled into the server. `LIST` is either a list of character set names separated by spaces, `complex` to include all character sets that can't be dynamically loaded, or `all` to include all character sets into the binaries.

- To configure MySQL with debugging code, use the `--with-debug` option:

```
shell> ./configure --with-debug
```

  This causes a safe memory allocator to be included that can find some errors and that provides output about what is happening. See Section F.1, "Debugging a MySQL Server".

- If your client programs are using threads, you also must compile a thread-safe version of the MySQL client library with the `--enable-thread-safe-client` configure option. This creates a `libmysqlclient_r` library with which you should link your threaded applications. See Section 23.2.15, "How to Make a Threaded Client".

- It is now possible to build MySQL with big table support using the `--with-big-tables` option, beginning with the following MySQL versions:

  - **4.0 series**: 4.0.25

  - **4.1 series**: 4.1.11

  - **5.0 series**: 5.0.4

  This option causes the variables used to keep table row counts to be stored using `unsigned long long` rather than `unsigned long`. What this does is to allow tables to hold up to approximately 1.844E+19 (($2^{32})^2$) rows rather than 2^{32} (~4.295E+09) rows. Previously it was necessary to pass `-DBIG_TABLES` to the compiler manually in order to enable this feature.

- Options that pertain to particular systems can be found in the system-specific section of this manual. See Section 2.12, "Operating System-Specific Notes".

2.8.3. Installing from the Development Source Tree

Caution: You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL up and running on your system, you should use a standard release distribution (either a binary or source distribution).

To obtain our most recent development source tree, use these instructions:

1. Download the BitKeeper free client from http://www.bitmover.com/bk-client.shar.

2. On Unix, install the free client like this:

```
shell> sh bk-client.shar
shell> cd bk_client-1.1
shell> make all
shell> PATH=$PWD:$PATH
```

On Windows, install it like this:

- Download and install Cygwin from http://cygwin.com [http://cygwin.com/].

- Make sure gcc has been installed under Cygwin. You can test this by issuing which gcc. If it's not installed, run Cygwin's package manager, select gcc, and install it.

- Under Cygwin, perform these steps:

```
shell> sh bk-client.shar
shell> cd bk_client-1.1
```

Then edit the Makefile and change the line that reads $(CC) $(CFLAGS) -o sfio -lz sfio.c to this:

```
$(CC) $(CFLAGS) -o sfio sfio.c -lz
```

Now run the make command and set the path:

```
shell> make all
shell> PATH=$PWD:$PATH
```

3. After the BitKeeper free client has been installed, first go to the directory you want to work from, and then use one of the following commands to make a local copy of the MySQL version branch of your choice:

To copy the 3.23 branch, use this command:

```
shell> sfioball -r+ bk://mysql.bkbits.net/mysql-3.23 mysql-3.23
```

To copy the 4.0 branch, use this command:

```
shell> sfioball -r+ bk://mysql.bkbits.net/mysql-4.0 mysql-4.0
```

To copy the 4.1 branch, use this command:

```
shell> sfioball -r+ bk://mysql.bkbits.net/mysql-4.1 mysql-4.1
```

To copy the 5.0 branch, use this command:

```
shell> sfioball -r+ bk://mysql.bkbits.net/mysql-5.0 mysql-5.0
```

Normally, you don't have to build the documentation yourself, because we're providing it in various formats on http://dev.mysql.com/doc/. The formats you can download there (HTML, PDF, etc.) are being built on a daily basis, so you gain little by creating them yourself from the DocBook XML base format in the mysqldoc tree. If you would like to copy the documentation repository, anyway, use the following command:

```
shell> sfioball -r+ bk://mysql.bkbits.net/mysqldoc mysqldoc
```

In the preceding examples, the source tree is set up in the `mysql-3.23/`, `mysql-4.0/`, `mysql-4.1/`, or `mysql-5.0/` subdirectory of your current directory.

The initial download of the source tree may take a while, depending on the speed of your connection. Please be patient.

4. To update the local copy of a repository, use this command (the example is for updating the 5.0 branch):

```
shell> update bk://mysql.bkbits.net/mysql-5.0 mysql-5.0
```

5. You need GNU `make`, `autoconf` 2.58 (or newer), `automake` 1.8, `libtool` 1.5, and `m4` to run the next set of commands. Even though many operating systems come with their own implementation of `make`, chances are high that the compilation fails with strange error messages. Therefore, it is highly recommended that you use GNU `make` (sometimes named `gmake`) instead.

Fortunately, a large number of operating systems ship with the GNU toolchain preinstalled or supply installable packages of these. In any case, they can also be downloaded from the following locations:

- http://www.gnu.org/software/autoconf/

- http://www.gnu.org/software/automake/

- http://www.gnu.org/software/libtool/

- http://www.gnu.org/software/m4/

- http://www.gnu.org/software/make/

If you are trying to configure MySQL 4.1 or later, you also need GNU `bison` 1.75 or later. Older versions of `bison` may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

Note: The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

Versions of MySQL before version 4.1 may also compile with other `yacc` implementations (for example, BSD `yacc` 91.7.30). For later versions, GNU `bison` is required.

The following example shows the typical commands required to configure a source tree. The first `cd` command changes location into the top-level directory of the tree; replace `mysql-5.0` with the appropriate directory name.

```
shell> cd mysql-5.0
shell> bk -r edit
shell> aclocal; autoheader
shell> libtoolize --automake --force
shell> automake --force --add-missing; autoconf
shell> (cd innobase; aclocal; autoheader; autoconf; automake)
shell> (cd bdb/dist; sh s_all)
shell> ./configure  # Add your favorite options here
shell> make
```

Or you can use `BUILD/autorun.sh` as a shortcut for the following sequence of commands:

```
shell> aclocal; autoheader
shell> libtoolize --automake --force
shell> automake --force --add-missing; autoconf
```

```
shell> (cd innobase; aclocal; autoheader; autoconf; automake)
shell> (cd bdb/dist; sh s_all)
```

The command lines that change directory into the `innobase` and `bdb/dist` directories are used to configure the `InnoDB` and Berkeley DB (`BDB`) storage engines. You can omit these command lines if you to not require `InnoDB` or `BDB` support.

If you get some strange errors during this stage, verify that you really have `libtool` installed.

A collection of our standard configuration scripts is located in the `BUILD/` subdirectory. You may find it more convenient to use the `BUILD/compile-pentium-debug` script than the preceding set of shell commands. To compile on a different architecture, modify the script by removing flags that are Pentium-specific.

6.   When the build is done, run `make install`. Be careful with this on a production machine; the command may overwrite your live release installation. If you have another installation of MySQL, we recommend that you run `./configure` with different values for the `--prefix`, `--with-tcp-port`, and `--unix-socket-path` options than those used for your production server.

7.   Play hard with your new installation and try to make the new features crash. Start by running `make test`. See Section 25.1.2, "MySQL Test Suite".

8.   If you have gotten to the `make` stage and the distribution does not compile, please report it in our bugs database at http://bugs.mysql.com/. If you have installed the latest versions of the required GNU tools, and they crash trying to process our configuration files, please report that also. However, if you execute `aclocal` and get a `command not found` error or a similar problem, do not report it. Instead, make sure that all the necessary tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

9.   After the initial copying of the repository (`sfioball`) to obtain the source tree, you should update the repository (`update`) periodically to get updates.

10.   You can examine the change history for the tree with all the diffs by viewing the `BK/ChangeLog` file in the source tree and looking at the `ChangeSet` descriptions listed there. To examine a particular changeset, you would have to use the `sfioball` command to extract two particular revisions of the source tree, then use an external `diff` command to compare them. If you see some funny diffs or code that you have a question about, do not hesitate to send email to the MySQL `internals` mailing list. See Section 1.7.1.1, "The MySQL Mailing Lists". Also, if you think you have a better idea on how to do something, send an email message to the same address with a patch.

11.   The BitKeeper free client is shipped with its source code. The only documentation available for the free client is the source code itself.

You can also browse changesets, comments, and source code online. For example, to browse this information for MySQL 5.0, go to http://mysql.bkbits.net:8080/mysql-5.0.

2.8.4. Dealing with Problems Compiling MySQL

All MySQL programs compile cleanly for us with no warnings on Solaris or Linux using `gcc`. On other systems, warnings may occur due to differences in system include files. See Section 2.8.5, "MIT-pthreads Notes" for warnings that may occur when using MIT-pthreads. For other problems, check the following list.

The solution to many problems involves reconfiguring. If you do need to reconfigure, take note of the following:

*   If `configure` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `config.cache`. When `config-`

ure starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

- Each time you run `configure`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old configuration information or object files from being used, run these commands before re-running `configure`:

```
shell> rm config.cache
shell> make clean
```

Alternatively, you can run `make distclean`.

The following list describes some of the problems when compiling MySQL that have been found to occur most often:

- If you get errors such as the ones shown here when compiling `sql_yacc.cc`, you probably have run out of memory or swap space:

```
Internal compiler error: program cc1plus got fatal signal 11
Out of virtual memory
Virtual memory exhausted
```

The problem is that `gcc` requires a huge amount of memory to compile `sql_yacc.cc` with inline functions. Try running `configure` with the `--with-low-memory` option:

```
shell> ./configure --with-low-memory
```

This option causes `-fno-inline` to be added to the compile line if you are using `gcc` and `-O0` if you are using something else. You should try the `--with-low-memory` option even if you have so much memory and swap space that you think you can't possibly have run out. This problem has been observed to occur even on systems with generous hardware configurations and the `--with-low-memory` option usually fixes it.

- By default, `configure` picks `c++` as the compiler name and GNU `c++` links with `-lg++`. If you are using `gcc`, that behavior can cause problems during configuration such as this:

```
configure: error: installation or configuration problem:
C++ compiler cannot create executables.
```

You might also observe problems during compilation related to `g++`, `libg++`, or `libstdc++`.

One cause of these problems is that you may not have `g++`, or you may have `g++` but not `libg++`, or `libstdc++`. Take a look at the `config.log` file. It should contain the exact reason why your C++ compiler didn't work. To work around these problems, you can use `gcc` as your C++ compiler. Try setting the environment variable `CXX` to `"gcc -O3"`. For example:

```
shell> CXX="gcc -O3" ./configure
```

This works because `gcc` compiles C++ sources as well as `g++` does, but does not link in `libg++` or `libstdc++` by default.

Another way to fix these problems is to install `g++`, `libg++`, and `libstdc++`. We would, however, like to recommend that you not use `libg++` or `libstdc++` with MySQL because this only increases the binary size of `mysqld` without giving you any benefits. Some versions of these libraries have also caused strange problems for MySQL users in the past.

Using gcc as the C++ compiler is also required if you want to compile MySQL with RAID functionality (see Section 13.1.5, "CREATE TABLE Syntax" for more info on RAID table type) and you are using GNU gcc version 3 and above. If you get errors like those following during the linking stage when you configure MySQL to compile with the option --with-raid, try to use gcc as your C++ compiler by defining the CXX environment variable:

```
gcc -O3 -DDBUG_OFF -rdynamic -o isamchk isamchk.o sort.o  libnisam.a
../mysys/libmysys.a ../dbug/libdbug.a ../strings/libmystrings.a
 -lpthread -lz -lcrypt -lnsl -lm -lpthread
../mysys/libmysys.a(raid.o)(.text+0x79): In function
`my_raid_create':: undefined reference to `operator new(unsigned)'
../mysys/libmysys.a(raid.o)(.text+0xdd): In function
`my_raid_create':: undefined reference to `operator delete(void*)'
../mysys/libmysys.a(raid.o)(.text+0x129): In function
`my_raid_open':: undefined reference to `operator new(unsigned)'
../mysys/libmysys.a(raid.o)(.text+0x189): In function
`my_raid_open':: undefined reference to `operator delete(void*)'
../mysys/libmysys.a(raid.o)(.text+0x64b): In function
`my_raid_close':: undefined reference to `operator delete(void*)'
collect2: ld returned 1 exit status
```

• If your compile fails with errors such as any of the following, you must upgrade your version of make to GNU make:

```
making all in mit-pthreads
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome make programs.

GNU make Version 3.75 is known to work.

• If you want to define flags to be used by your C or C++ compilers, do so by adding the flags to the CFLAGS and CXXFLAGS environment variables. You can also specify the compiler names this way using CC and CXX. For example:

```
shell> CC=gcc
shell> CFLAGS=-O3
shell> CXX=gcc
shell> CXXFLAGS=-O3
shell> export CC CFLAGS CXX CXXFLAGS
```

See Section 2.1.2.5, "MySQL Binaries Compiled by MySQL AB", for a list of flag definitions that have been found to be useful on various systems.

• If you get an error message like this, you need to upgrade your gcc compiler:

```
client/libmysql.c:273: parse error before `__attribute__'
```

gcc 2.8.1 is known to work, but we recommend using gcc 2.95.2 or egcs 1.0.3a instead.

• If you get errors such as those shown here when compiling mysqld, configure didn't cor-

rectly detect the type of the last argument to `accept()`, `getsockname()`, or `getpeer-name()`:

```
cxx: Error: mysqld.cc, line 645: In this statement, the referenced
     type of the pointer value ''length'' is ''unsigned long'',
     which is not compatible with ''int''.
new_sock = accept(sock, (struct sockaddr *)&cAddr, &length);
```

To fix this, edit the `config.h` file (which is generated by `configure`). Look for these lines:

```
/* Define as the base type of the last arg to accept */
#define SOCKET_SIZE_TYPE XXX
```

Change XXX to `size_t` or `int`, depending on your operating system. (Note that you have to do this each time you run `configure` because `configure` regenerates `config.h`.)

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally the build process doesn't need to create `sql_yacc.cc`, because MySQL comes with an pre-generated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of `yacc` is deficient. You probably need to install `bison` (the GNU version of `yacc`) and use that instead.

- On Debian Linux 3.0, you need to install `gawk` instead of the default `mawk` if you want to compile MySQL 4.1 or higher with Berkeley DB support.

- If you need to debug `mysqld` or a MySQL client, run `configure` with the `--with-debug` option, then recompile and link your clients with the new client library. See Section F.2, "Debugging a MySQL Client".

- If you get a compilation error on Linux (for example, SuSE Linux 8.1 or Red Hat Linux 7.3) similar to the following one:

```
libmysql.c:1329: warning: passing arg 5 of `gethostbyname_r' from
incompatible pointer type
libmysql.c:1329: too few arguments to function `gethostbyname_r'
libmysql.c:1329: warning: assignment makes pointer from integer
without a cast
make[2]: *** [libmysql.lo] Error 1
```

By default, the `configure` script attempts to determine the correct number of arguments by using `g++` the GNU C++ compiler. This test yields wrong results if `g++` is not installed. There are two ways to work around this problem:

- Make sure that the GNU C++ `g++` is installed. On some Linux distributions, the required package is called `gpp`; on others, it is named `gcc-c++`.

- Use `gcc` as your C++ compiler by setting the `CXX` environment variable to `gcc`:

```
export CXX="gcc"
```

Please note that you need to run `configure` again afterward.

2.8.5. MIT-pthreads Notes

This section describes some of the issues involved in using MIT-pthreads.

On Linux, you should *not* use MIT-pthreads. Use the installed LinuxThreads implementation instead. See Section 2.12.1, "Linux Notes".

If your system does not provide native thread support, you need to build MySQL using the MIT-pthreads package. This includes older FreeBSD systems, SunOS 4.x, Solaris 2.4 and earlier, and some others. See Section 2.1.1, "Operating Systems Supported by MySQL".

Beginning with MySQL 4.0.2, MIT-pthreads is no longer part of the source distribution. If you require this package, you need to download it separately from ht-tp://www.mysql.com/Downloads/Contrib/pthreads-1_60_beta6-mysql.tar.gz

After downloading, extract this source archive into the top level of the MySQL source directory. It creates a new subdirectory named `mit-pthreads`.

- On most systems, you can force MIT-pthreads to be used by running `configure` with the `--with-mit-threads` option:

  ```
  shell> ./configure --with-mit-threads
  ```

  Building in a non-source directory is not supported when using MIT-pthreads because we want to minimize our changes to this code.

- The checks that determine whether to use MIT-pthreads occur only during the part of the configuration process that deals with the server code. If you have configured the distribution using `--without-server` to build only the client code, clients do not know whether MIT-pthreads is being used and use Unix socket connections by default. Because Unix socket files do not work under MIT-pthreads on some platforms, this means you need to use `-h` or `--host` when you run client programs.

- When MySQL is compiled using MIT-pthreads, system locking is disabled by default for performance reasons. You can tell the server to use system locking with the `--external-locking` option. This is needed only if you want to be able to run two MySQL servers against the same data files, which is not recommended.

- Sometimes the pthread `bind()` command fails to bind to a socket without any error message (at least on Solaris). The result is that all connections to the server fail. For example:

  ```
  shell> mysqladmin version
  mysqladmin: connect to server at '' failed;
  error: 'Can't connect to mysql server on localhost (146)'
  ```

  The solution to this is to kill the `mysqld` server and restart it. This has only happened to us when we have forced down the server and done a restart immediately.

- With MIT-pthreads, the `sleep()` system call isn't interruptible with `SIGINT` (break). This is only noticeable when you run `mysqladmin --sleep`. You must wait for the `sleep()` call to terminate before the interrupt is served and the process stops.

- When linking, you may receive warning messages like these (at least on Solaris); they can be ignored:

  ```
  ld: warning: symbol `_iob' has differing sizes:
      (file /my/local/pthreads/lib/libpthread.a(findfp.o) value=0x4;
  file /usr/lib/libc.so value=0x140);
      /my/local/pthreads/lib/libpthread.a(findfp.o) definition taken
  ld: warning: symbol `__iob' has differing sizes:
      (file /my/local/pthreads/lib/libpthread.a(findfp.o) value=0x4;
  file /usr/lib/libc.so value=0x140);
      /my/local/pthreads/lib/libpthread.a(findfp.o) definition taken
  ```

- Some other warnings also can be ignored:

```
implicit declaration of function `int strtoll(...)'
implicit declaration of function `int strtoul(...)'
```

- We haven't gotten `readline` to work with MIT-pthreads. (This isn't needed, but may be interesting for someone.)

2.8.6. Installing MySQL from Source on Windows

These instructions describe how to build MySQL binaries from source for versions 4.1 and above on Windows. Instructions are provided for building binaries from a standard source distribution or from the BitKeeper tree that contains the latest development source.

Note: The instructions in this document are strictly for users who want to test MySQL on Windows from the latest source distribution or from the BitKeeper tree. For production use, MySQL AB does not advise using a MySQL server built by yourself from source. Normally, it is best to use precompiled binary distributions of MySQL that are built specifically for optimal performance on Windows by MySQL AB. Instructions for installing a binary distributions are available at Section 2.3, "Installing MySQL on Windows".

To build MySQL on Windows from source, you need the following compiler and resources available on your Windows system:

- VC++ 6.0 compiler (updated with 4 or 5 SP and pre-processor package). The pre-processor package is necessary for the macro assembler. More details can be found at http://msdn.microsoft.com/vstudio/downloads/updates/sp/vs6/sp5/faq.aspx.

- Approximately 45MB disk space.

- 64MB RAM.

You'll also need a MySQL source distribution for Windows. There are two ways you can get a source distribution for MySQL version 4.1 and above:

1. Obtain a source distribution packaged by MySQL AB for the particular version of MySQL in which you are interested. Prepackaged source distributions are available for released versions of MySQL and can be obtained from http://dev.mysql.com/downloads/.

2. You can package a source distribution yourself from the latest BitKeeper developer source tree. If you plan to do this, you must create the package on a Unix system and then transfer it to your Windows system. (The reason for this is that some of the configuration and build steps require tools that work only on Unix.) The BitKeeper approach thus requires:

   - A system running Unix, or a Unix-like system such as Linux.

   - BitKeeper 3.0 installed on that system. See Section 2.8.3, "Installing from the Development Source Tree" for instructions how to download and install BitKeeper.

If you are using a Windows source distribution, you can go directly to Section 2.8.6.1, "Building MySQL Using VC++". To build from the BitKeeper tree, proceed to Section 2.8.6.2, "Creating a Windows Source Package from the Latest Development Source".

If you find something not working as expected, or you have suggestions about ways to improve the current build process on Windows, please send a message to the `win32` mailing list. See Section 1.7.1.1, "The MySQL Mailing Lists".

2.8.6.1. Building MySQL Using VC++

Note: VC++ workspace files for MySQL 4.1 and above are compatible with Microsoft Visual Studio 6.0 and above (7.0/.NET) editions and tested by MySQL AB staff before each release.

Follow this procedure to build MySQL:

1. Create a work directory (for example, `C:\workdir`).

2. Unpack the source distribution in the aforementioned directory using `WinZip` or other Windows tool that can read `.zip` files.

3. Start Visual Studio.

4. In the `File` menu, select `Open Workspace`.

5. Open the `mysql.dsw` workspace you find in the work directory.

6. From the `Build` menu, select the `Set Active Configuration` menu.

7. Click over the screen selecting `mysqld - Win32 Debug` and click OK.

8. Press `F7` to begin the build of the debug server, libraries, and some client applications.

9. Compile the release versions that you want in the same way.

10. Debug versions of the programs and libraries are placed in the `client_debug` and `lib_debug` directories. Release versions of the programs and libraries are placed in the `client_release` and `lib_release` directories. Note that if you want to build both debug and release versions, you can select the `Build All` option from the `Build` menu.

11. Test the server. The server built using the preceding instructions expects that the MySQL base directory and data directory are `C:\mysql` and `C:\mysql\data` by default. If you want to test your server using the source tree root directory and its data directory as the base directory and data directory, you need to tell the server their pathnames. You can either do this on the command line with the `--basedir` and `--datadir` options, or place appropriate options in an option file (the `my.ini` file in your Windows directory or `C:\my.cnf`). If you have an existing data directory elsewhere that you want to use, you can specify its pathname instead.

12. Start your server from the `client_release` or `client_debug` directory, depending on which server you want to use. The general server startup instructions are at Section 2.3, "Installing MySQL on Windows". You'll need to adapt the instructions appropriately if you want to use a different base directory or data directory.

13. When the server is running in standalone fashion or as a service based on your configuration, try to connect to it from the `mysql` interactive command-line utility that exists in your `client_release` or `client_debug` directory.

When you are satisfied that the programs you have built are working correctly, stop the server. Then install MySQL as follows:

1. Create the directories where you want to install MySQL. For example, to install into `C:\mysql`, use these commands:

```
C:\> mkdir C:\mysql
C:\> mkdir C:\mysql\bin
C:\> mkdir C:\mysql\data
C:\> mkdir C:\mysql\share
C:\> mkdir C:\mysql\scripts
```

If you want to compile other clients and link them to MySQL, you should also create several additional directories:

```
C:\> mkdir C:\mysql\include
C:\> mkdir C:\mysql\lib
C:\> mkdir C:\mysql\lib\debug
C:\> mkdir C:\mysql\lib\opt
```

If you want to benchmark MySQL, create this directory:

```
C:\> mkdir C:\mysql\sql-bench
```

Benchmarking requires Perl support.

2. From the `workdir` directory, copy into the `C:\mysql` directory the following directories:

```
C:\> cd \workdir
C:\workdir> copy client_release\*.exe C:\mysql\bin
C:\workdir> copy client_debug\mysqld.exe C:\mysql\bin\mysqld-debug.exe
C:\workdir> xcopy scripts\*.* C:\mysql\scripts /E
C:\workdir> xcopy share\*.* C:\mysql\share /E
```

If you want to compile other clients and link them to MySQL, you should also copy several libraries and header files:

```
C:\workdir> copy lib_debug\mysqlclient.lib C:\mysql\lib\debug
C:\workdir> copy lib_debug\libmysql.* C:\mysql\lib\debug
C:\workdir> copy lib_debug\zlib.* C:\mysql\lib\debug
C:\workdir> copy lib_release\mysqlclient.lib C:\mysql\lib\opt
C:\workdir> copy lib_release\libmysql.* C:\mysql\lib\opt
C:\workdir> copy lib_release\zlib.* C:\mysql\lib\opt
C:\workdir> copy include\*.h C:\mysql\include
C:\workdir> copy libmysql\libmysql.def C:\mysql\include
```

If you want to benchmark MySQL, you should also do this:

```
C:\workdir> xcopy sql-bench\*.* C:\mysql\bench /E
```

Set up and start the server in the same way as for the binary Windows distribution. See Section 2.3, "Installing MySQL on Windows".

2.8.6.2. Creating a Windows Source Package from the Latest Development Source

To create a Windows source package from the current BitKeeper source tree, use the following instructions. Please note that this procedure must be performed on a system running a Unix or Unix-like operating system. For example, the procedure is known to work well on Linux.

1. Copy the BitKeeper source tree for MySQL (version 4.1 or above, as desired). For more information on how To copy the source tree, see the instructions at Section 2.8.3, "Installing from the Development Source Tree".

2. Configure and build the distribution so that you have a server binary to work with. One way to do this is to run the following command in the top-level directory of your source tree:

```
shell> ./BUILD/compile-pentium-max
```

3. After making sure that the build process completed successfully, run the following utility script from top-level directory of your source tree:

```
shell> ./scripts/make_win_src_distribution
```

This script creates a Windows source package to be used on your Windows system. You can supply different options to the script based on your needs. It accepts the following options:

- `--help`

  Display a help message.

- `--debug`

  Print information about script operations, do not create package.

- `--tmp`

  Specify the temporary location.

- `--suffix`

  Suffix name for the package.

- `--dirname`

  Directory name to copy files (intermediate).

- `--silent`

  Do not print verbose list of files processed.

- `--tar`

  Create `tar.gz` package instead of `.zip` package.

By default, `make_win_src_distribution` creates a Zip-format archive with the name `mysql-VERSION-win-src.zip`, where `VERSION` represents the version of your MySQL source tree.

4. Copy or upload to your Windows machine the Windows source package that you have just created. To compile it, use the instructions in Section 2.8.6.1, "Building MySQL Using VC++".

2.8.7. Compiling MySQL Clients on Windows

In your source files, you should include `my_global.h` before `mysql.h`:

```
#include <my_global.h>
#include <mysql.h>
```

`my_global.h` includes any other files needed for Windows compatibility (such as `windows.h`) if you compile your program on Windows.

You can either link your code with the dynamic `libmysql.lib` library, which is just a wrapper to load in `libmysql.dll` on demand, or link with the static `mysqlclient.lib` library.

The MySQL client libraries are compiled as threaded libraries, so you should also compile your code to be multi-threaded.

2.9. Post-Installation Setup and Testing

After installing MySQL, there are some issues you should address. For example, on Unix, you

should initialize the data directory and create the MySQL grant tables. On all platforms, an important security concern is that the initial accounts in the grant tables have no passwords. You should assign passwords to prevent unauthorized access to the MySQL server. For MySQL 4.1.3 and up, you can create time zone tables to enable recognition of named time zones. (Currently, these tables can be populated only on Unix. This problem will be addressed soon for Windows.)

The following sections include post-installation procedures that are specific to Windows systems and to Unix systems. Another section, Section 2.9.2.3, "Starting and Troubleshooting the MySQL Server", applies to all platforms; it describes what to do if you have trouble getting the server to start. Section 2.9.3, "Securing the Initial MySQL Accounts" also applies to all platforms. You should follow its instructions to make sure that you have properly protected your MySQL accounts by assigning passwords to them.

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in Section 5.6, "The MySQL Access Privilege System" and Section 5.7, "MySQL User Account Management".

2.9.1. Windows Post-Installation Procedures

On Windows, the data directory and the grant tables do not have to be created. MySQL Windows distributions include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory. You do not run the `mysql_install_db` script that is used on Unix. However, if you did not install MySQL using the Windows Installation Wizard, you should assign passwords to the accounts. See Section 2.3.4.1, "Introduction". The procedure for this is given in Section 2.9.3, "Securing the Initial MySQL Accounts".

Before setting up passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure the server is running (see Section 2.3.10, "Starting the Server for the First Time"), then issue the following commands to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
C:\> C:\mysql\bin\mysqlshow
+-----------+
| Databases |
+-----------+
| mysql     |
| test      |
+-----------+

C:\> C:\mysql\bin\mysqlshow mysql
Database: mysql
+--------------+
|    Tables    |
+--------------+
| columns_priv |
| db           |
| func         |
| host         |
| tables_priv  |
| user         |
+--------------+

C:\> C:\mysql\bin\mysql -e "SELECT Host,Db,User FROM db" mysql
+------+-------+------+
| host | db    | user |
+------+-------+------+
| %    | test% |      |
+------+-------+------+
```

If you are running a version of Windows that supports services and you want the MySQL server to run automatically when Windows starts, see Section 2.3.12, "Starting MySQL as a Windows Service".

2.9.2. Unix Post-Installation Procedures

After installing MySQL on Unix, you need to initialize the grant tables, start the server, and make sure that the server works okay. You may also wish to arrange for the server to be started and stopped automatically when your system starts and stops. You should also assign passwords to the accounts in the grant tables.

On Unix, the grant tables are set up by the `mysql_install_db` program. For some installation methods, this program is run for you automatically:

- If you install MySQL on Linux using RPM distributions, the server RPM runs `mysql_install_db`.

- If you install MySQL on Mac OS X using a PKG distribution, the installer runs `mysql_install_db`.

Otherwise, you'll need to run `mysql_install_db` yourself.

The following procedure describes how to initialize the grant tables (if that has not previously been done) and then start the server. It also suggests some commands that you can use to test whether the server is accessible and working properly. For information about starting and stopping the server automatically, see Section 2.9.2.2, "Starting and Stopping MySQL Automatically".

After you complete the procedure and have the server running, you should assign passwords to the accounts created by `mysql_install_db`. Instructions for doing so are given in Section 2.9.3, "Securing the Initial MySQL Accounts".

In the examples shown here, the server runs under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server.

1. Change location into the top-level directory of your MySQL installation, represented here by *BASEDIR*:

   ```
   shell> cd BASEDIR
   ```

   BASEDIR is likely to be something like `/usr/local/mysql` or `/usr/local`. The following steps assume that you are located in this directory.

2. If necessary, run the `mysql_install_db` program to set up the initial MySQL grant tables containing the privileges that determine how users are allowed to connect to the server. You'll need to do this if you used a distribution type that doesn't run the program for you.

   Typically, `mysql_install_db` needs to be run only the first time you install MySQL, so you can skip this step if you are upgrading an existing installation, However, `mysql_install_db` does not overwrite any existing privilege tables, so it should be safe to run in any circumstances.

   To initialize the grant tables, use one of the following commands, depending on whether `mysql_install_db` is located in the `bin` or `scripts` directory:

   ```
   shell> bin/mysql_install_db --user=mysql
   shell> scripts/mysql_install_db --user=mysql
   ```

   The `mysql_install_db` script creates the data directory, the `mysql` database that holds all database privileges, and the `test` database that you can use to test MySQL. The script also creates privilege table entries for `root` accounts and anonymous-user accounts. The accounts have no passwords initially. A description of their initial privileges is given in Section 2.9.3, "Securing the Initial MySQL Accounts". Briefly, these privileges allow the MySQL `root` user

to do anything, and allow anybody to create or use databases with a name of `test` or starting with `test_`.

It is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this, the `--user` option should be used as shown if you run `mysql_install_db` as `root`. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` option from the command.

`mysql_install_db` creates several tables in the `mysql` database: `user`, `db`, `host`, `tables_priv`, `columns_priv`, `func`, and possibly others depending on your version of MySQL.

If you don't want to have the `test` database, you can remove it with `mysqladmin -u root drop test` after starting the server.

If you have problems with `mysql_install_db`, see Section 2.9.2.1, "Problems Running `mysql_install_db`".

There are some alternatives to running the `mysql_install_db` script as it is provided in the MySQL distribution:

- If you want the initial privileges to be different from the standard defaults, you can modify `mysql_install_db` before you run it. However, a preferable technique is to use `GRANT` and `REVOKE` to change the privileges after the grant tables have been set up. In other words, you can run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL `root` user so that you can issue the `GRANT` and `REVOKE` statements.

  If you want to install MySQL on a lot of machines with the same privileges, you can put the `GRANT` and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

  ```
  shell> bin/mysql_install_db --user=mysql
  shell> bin/mysql -u root < your_script_file
  ```

  By doing this, you can avoid having to issue the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you're just learning how to use `GRANT` and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

  To re-create the grant tables, remove all the `.frm`, `.MYI`, and `.MYD` files in the directory containing the `mysql` database. (This is the directory named `mysql` under the data directory, which is listed as the `datadir` value when you run `mysqld --help`.) Then run the `mysql_install_db` script again.

  Note: For MySQL versions older than 3.22.10, you should not delete the `.frm` files. If you accidentally do this, you should copy them back into the `mysql` directory from your MySQL distribution before running `mysql_install_db`.

- You can start `mysqld` manually using the `--skip-grant-tables` option and add the privilege information yourself using `mysql`:

  ```
  shell> bin/mysqld_safe --user=mysql --skip-grant-tables &
  shell> bin/mysql mysql
  ```

  From `mysql`, manually execute the SQL commands contained in `mysql_install_db`. Make sure that you run `mysqladmin flush-privileges` or `mysqladmin reload` afterward to tell the server to reload the grant tables.

Note that by not using `mysql_install_db`, you not only have to populate the grant tables manually, you also have to create them first.

3. Start the MySQL server:

```
shell> bin/mysqld_safe --user=mysql &
```

For versions of MySQL older than 4.0, substitute `bin/safe_mysqld` for `bin/mysqld_safe` in this command.

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this, the `--user` option should be used as shown if you run `mysql_safe` as `root`. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` option from the command.

Further instructions for running MySQL as an unprivileged user are given in Section A.3.2, "How to Run MySQL as a Normal User".

If you neglected to create the grant tables before proceeding to this step, the following message appears in the error log file when you start the server:

```
mysqld: Can't find file: 'host.frm'
```

If you have other problems starting the server, see Section 2.9.2.3, "Starting and Troubleshooting the MySQL Server".

4. Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin  Ver 8.40 Distrib 4.0.18, for linux on i586
Copyright (C) 2000 MySQL AB & MySQL Finland AB & TCX DataKonsult AB
This software comes with ABSOLUTELY NO WARRANTY. This is free software,
and you are welcome to modify and redistribute it under the GPL license

Server version          4.0.18-log
Protocol version        10
Connection              Localhost via Unix socket
TCP port                3306
UNIX socket             /tmp/mysql.sock
Uptime:                 16 sec

Opens: 7  Flush tables: 2  Open tables: 0
Queries per second avg: 0.000
Memory in use: 132K  Max memory used: 16773K
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

5. Verify that you can shut down the server:

```
shell> bin/mysqladmin -u root shutdown
```

6. Verify that you can restart the server. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
shell> bin/mysqld_safe --user=mysql --log &
```

If `mysqld_safe` fails, see Section 2.9.2.3, "Starting and Troubleshooting the MySQL Server".

7. Run some simple tests to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
shell> bin/mysqlshow
+-----------+
| Databases |
+-----------+
| mysql     |
| test      |
+-----------+

shell> bin/mysqlshow mysql
Database: mysql
+--------------+
|    Tables    |
+--------------+
| columns_priv |
| db           |
| func         |
| host         |
| tables_priv  |
| user         |
+--------------+

shell> bin/mysql -e "SELECT Host,Db,User FROM db" mysql
+------+--------+------+
| host | db     | user |
+------+--------+------+
| %    | test   |      |
| %    | test_% |      |
+------+--------+------+
```

8. There is a benchmark suite in the `sql-bench` directory (under the MySQL installation directory) that you can use to compare how MySQL performs on different platforms. The benchmark suite is written in Perl. It uses the Perl DBI module to provide a database-independent interface to the various databases, and some other additional Perl modules are required to run the benchmark suite. You must have the following modules installed:

```
DBI
DBD::mysql
Data::Dumper
Data::ShowTable
```

These modules can be obtained from CPAN (http://www.cpan.org/). See Section 2.13.1, "Installing Perl on Unix".

The `sql-bench/Results` directory contains the results from many runs against different databases and platforms. To run all tests, execute these commands:

```
shell> cd sql-bench
shell> perl run-all-tests
```

If you don't have the `sql-bench` directory, you probably installed MySQL using RPM files other than the source RPM. (The source RPM includes the `sql-bench` benchmark directory.) In this case, you must first install the benchmark suite before you can use it. Beginning with

MySQL 3.22, there are separate benchmark RPM files named `mysql-bench-VERSION-i386.rpm` that contain benchmark code and data.

If you have a source distribution, there are also tests in its `tests` subdirectory that you can run. For example, to run `auto_increment.tst`, execute this command from the top-level directory of your source distribution:

```
shell> mysql -vvf test < ./tests/auto_increment.tst
```

The expected result of the test can be found in the `./tests/auto_increment.res` file.

9. At this point, you should have the server running. However, none of the initial MySQL accounts have a password, so you should assign passwords using the instructions in Section 2.9.3, "Securing the Initial MySQL Accounts".

As of MySQL 4.1.3, the installation procedure creates time zone tables in the `mysql` database. However, you must populate the tables manually. Instructions to do this are given in Section 5.9.8, "MySQL Server Time Zone Support".

2.9.2.1. Problems Running `mysql_install_db`

The purpose of the `mysql_install_db` script is to generate new MySQL privilege tables. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

If you want to re-create your privilege tables, first stop the `mysqld` server if it's running. Then rename the `mysql` directory under the data directory to save it, and then run `mysql_install_db`. For example:

```
shell> mv mysql-data-directory/mysql mysql-data-directory/mysql-old
shell> mysql_install_db --user=mysql
```

This section lists problems you might encounter when you run `mysql_install_db`:

- **`mysql_install_db` doesn't install the grant tables**

    You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

    ```
    Starting mysqld daemon with databases from XXXXXX
    mysqld ended
    ```

    In this case, you should examine the error log file very carefully. The log should be located in the directory `XXXXXX` named by the error message, and should indicate why `mysqld` didn't start. If you don't understand what happened, include the log when you post a bug report. See Section 1.7.1.3, "How to Report Bugs or Problems".

- **There is a `mysqld` process running**

    This indicates that the server is running, in which case the grant tables have probably been created. If so, you don't have to run `mysql_install_db` at all because it need be run only once (when you install MySQL the first time).

- **Installing a second `mysqld` server doesn't work when one server is running**

    This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

```
Can't start server: Bind on TCP/IP port:
Address already in use
Can't start server: Bind on unix socket...
```

For instructions on setting up multiple servers, see Section 5.11, "Running Multiple MySQL Servers on the Same Machine".

- **You don't have write access to `/tmp`**

  If you don't have write access to create temporary files or a Unix socket file in the default location (the `/tmp` directory), an error occurs when you run `mysql_install_db` or the `mysqld` server.

  You can specify different temporary directory and Unix socket file locations by executing these commands prior to starting `mysql_install_db` or `mysqld`:

  ```
  shell> TMPDIR=/some_tmp_dir/
  shell> MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
  shell> export TMPDIR MYSQL_UNIX_PORT
  ```

  `some_tmp_dir` should be the full pathname to some directory for which you have write permission.

  After this, you should be able to run `mysql_install_db` and start the server with these commands:

  ```
  shell> bin/mysql_install_db --user=mysql
  shell> bin/mysqld_safe --user=mysql &
  ```

  If `mysql_install_db` is located in the `scripts` directory, modify the first command to use `scripts/mysql_install_db`.

  See Section A.4.5, "How to Protect or Change the MySQL Socket File `/tmp/mysql.sock`". See Appendix G, *Environment Variables*.

2.9.2.2. Starting and Stopping MySQL Automatically

Generally, you start the `mysqld` server in one of these ways:

- By invoking `mysqld` directly. This works on any platform.

- By running the MySQL server as a Windows service. This can be done on versions of Windows that support services (such as NT, 2000, XP, and 2003). The service can be set to start the server automatically when Windows starts, or as a manual service that you start on request. For instructions, see Section 2.3.12, "Starting MySQL as a Windows Service".

- By invoking `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. This script is used on systems based on BSD Unix. See Section 5.1.3, "mysqld_safe — MySQL Server Startup Script".

- By invoking `mysql.server`. This script is used primarily at system startup and shutdown on systems that use System V-style run directories, where it usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See Section 5.1.4, "mysql.server — MySQL Server Startup Script".

- On Mac OS X, you can install a separate MySQL Startup Item package to enable the automatic startup of MySQL on system startup. The Startup Item starts the server by invoking

mysql.server. See Section 2.5, "Installing MySQL on Mac OS X" for details.

The mysql.server and mysqld_safe scripts and the Mac OS X Startup Item can be used to start the server manually, or automatically at system startup time. mysql.server and the Startup Item also can be used to stop the server.

To start or stop the server manually using the mysql.server script, invoke it with start or stop arguments:

```
shell> mysql.server start
shell> mysql.server stop
```

Before mysql.server starts the server, it changes location to the MySQL installation directory, and then invokes mysqld_safe. If you want the server to run as some specific user, add an appropriate user option to the [mysqld] group of the /etc/my.cnf option file, as shown later in this section. (It is possible that you'll need to edit mysql.server if you've installed a binary distribution of MySQL in a non-standard location. Modify it to cd into the proper directory before it runs mysqld_safe. If you do this, your modified version of mysql.server may be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.)

mysql.server stop brings down the server by sending a signal to it. You can also stop the server manually by executing mysqladmin shutdown.

To start and stop MySQL automatically on your server, you need to add start and stop commands to the appropriate places in your /etc/rc* files.

If you use the Linux server RPM package (MySQL-server-VERSION.rpm), the mysql.server script is installed in the /etc/init.d directory with the name mysql. You need not install it manually. See Section 2.4, "Installing MySQL on Linux" for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as mysqld.

If you install MySQL from a source distribution or using a binary distribution format that does not install mysql.server automatically, you can install it manually. The script can be found in the support-files directory under the MySQL installation directory or in a MySQL source tree.

To install mysql.server manually, copy it to the /etc/init.d directory with the name mysql, and then make it executable. Do this by changing location into the appropriate directory where mysql.server is located and executing these commands:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

Older Red Hat systems use the /etc/rc.d/init.d directory rather than /etc/init.d. Adjust the preceding commands accordingly. Alternatively, first create /etc/init.d as a symbolic link that points to /etc/rc.d/init.d:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use chkconfig:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the mysql script:

```
shell> chkconfig --level 345 mysql on
```

On FreeBSD, startup scripts generally should go in /usr/local/etc/rc.d/. The rc(8) manual page states that scripts in this directory are executed only if their basename matches the *.sh shell filename pattern. Any other files or directories present within the directory are silently ignored. In other words, on FreeBSD, you should install the mysql.server script as / usr/local/etc/rc.d/mysql.server.sh to enable automatic startup.

As an alternative to the preceding setup, some operating systems also use /etc/rc.local or / etc/init.d/boot.local to start additional services on startup. To start up MySQL using this method, you could append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

You can add options for mysql.server in a global /etc/my.cnf file. A typical / etc/my.cnf file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The mysql.server script understands the following options: basedir, datadir, and pid-file. If specified, they *must* be placed in an option file, not on the command line. mysql.server understands only start and stop as command-line arguments.

The following table shows which option groups the server and each startup script read from option files:

Script	Option Groups
mysqld	[mysqld], [server], [mysqld-major-version]
mysql.server	[mysqld], [mysql.server]
mysqld_safe	[mysqld], [server], [mysqld_safe]

[mysqld-major-version] means that groups with names like [mysqld-4.0], [mysqld-4.1], and [mysqld-5.0] are read by servers having versions 4.0.x, 4.1.x, 5.0.x, and so forth. This feature was added in MySQL 4.0.14. It can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, mysql.server also reads the [mysql_server] group and mysqld_safe also reads the [safe_mysqld] group. However, you should update your option files to use the [mysql.server] and [mysqld_safe] groups instead when you begin using MySQL 4.0 or later.

See Section 4.3.2, "Using Option Files".

2.9.2.3. Starting and Troubleshooting the MySQL Server

If you have problems starting the server, here are some things you can try:

• Specify any special options needed by the storage engines you are using.

- Make sure that the server knows where to find the data directory.

- Make sure the server can use the data directory. The ownership and permissions of the data directory and its contents must be set such that the server can access and modify them.

- Check the error log to see why the server doesn't start.

- Verify that the network interfaces the server wants to use are available.

Some storage engines have options that control their behavior. You can create a `my.cnf` file and set startup options for the engines you plan to use. If you are going to use storage engines that support transactional tables (`InnoDB`, `BDB`), be sure that you have them configured the way you want before starting the server:

- If you are using `InnoDB` tables, refer to the `InnoDB`-specific startup options. In MySQL 3.23, you must configure `InnoDB` explicitly or the server fails to start. From MySQL 4.0 on, `InnoDB` uses default values for its configuration options if you specify none. See Section 15.4, "`InnoDB` Configuration".

- If you are using `BDB` (Berkeley DB) tables, you should familiarize yourself with the different `BDB`-specific startup options. See Section 14.4.3, "`BDB` Startup Options".

When the `mysqld` server starts, it changes location to the data directory. This is where it expects to find databases and where it expects to write log files. On Unix, the server also writes the pid (process ID) file in the data directory.

The data directory location is hardwired in when the server is compiled. This is where the server looks for the data directory by default. If the data directory is located somewhere else on your system, the server does not work properly. You can find out what the default path settings are by invoking `mysqld` with the `--verbose` and `--help` options. (Prior to MySQL 4.1, omit the `--verbose` option.)

If the defaults don't match the MySQL installation layout on your system, you can override them by specifying options on the command line to `mysqld` or `mysqld_safe`. You can also list the options in an option file.

To specify the location of the data directory explicitly, use the `--datadir` option. However, normally you can tell `mysqld` the location of the base directory under which MySQL is installed and it looks for the data directory there. You can do this with the `--basedir` option.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location into the directory where `mysqld` is installed, and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but note that `--verbose` and `--help` must be the last options. (Prior to MySQL 4.1, omit the `--verbose` option.)

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

host_name is the name of the MySQL server host.

If you get Errcode 13 (which means Permission denied) when starting mysqld, this means that the access privileges of the data directory or its contents do not allow the server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as root, but this can raise security issues and should be avoided.

On Unix, change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is /usr/local/mysql/var, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the account that you use for running the server, change their ownership to that account:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

If the server fails to start up correctly, check the error log file to see if you can find out why. Log files are located in the data directory (typically C:\mysql\data on Windows, /usr/local/mysql/data for a Unix binary distribution, and /usr/local/var for a Unix source distribution). Look in the data directory for files with names of the form *host_name*.err and *host_name*.log, where *host_name* is the name of your server host. (Older servers on Windows use mysql.err as the error log name.) Then check the last few lines of these files. On Unix, you can use tail to display the last few lines:

```
shell> tail host_name.err
shell> tail host_name.log
```

The error log contains information that indicates why the server couldn't start. For example, you might see something like this in the log:

```
000729 14:50:10  bdb:  Recovery function for LSN 1 27595 failed
000729 14:50:10  bdb:  warning: ./test/t1.db: No such file or directory
000729 14:50:10  Can't init databases
```

This means that you didn't start mysqld with the --bdb-no-recover option and Berkeley DB found something wrong with its own log files when it tried to recover your databases. To be able to continue, you should move away the old Berkeley DB log files from the database directory to some other place, where you can later examine them. The BDB log files are named in sequence beginning with log.0000000001, where the number increases over time.

If you are running mysqld with BDB table support and mysqld dumps core at startup, this could be due to problems with the BDB recovery log. In this case, you can try starting mysqld with --bdb-no-recover. If that helps, then you should remove all BDB log files from the data directory and try starting mysqld again without the --bdb-no-recover option.

If either of the following errors occur, it means that some other program (perhaps another mysqld server) is using the TCP/IP port or Unix socket file that mysqld is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use ps to determine whether you have another mysqld server running. If so, shut down the server before starting mysqld again. (If another server is running, and you really want to run multiple

servers, you can find information about how to do so in Section 5.11, "Running Multiple MySQL Servers on the Same Machine".)

If no other server is running, try to execute the command `telnet your-host-name tcp-ip-port-number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you don't get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. You'll need to track down what program this is and disable it, or else tell `mysqld` to listen to a different port with the `--port` option. In this case, you'll also need to specify the port number for client programs when connecting to the server via TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to allow access to the port.

If the server starts but you can't connect to it, you should make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1        localhost
```

This problem occurs only on systems that don't have a working thread library and for which MySQL must be configured to use MIT-pthreads.

If you can't get `mysqld` to start, you can try to make a trace file to find the problem by using the `--debug` option. See Section F.1.2, "Creating Trace Files".

See Section 2.3.14, "Troubleshooting a MySQL Installation Under Windows", for more information on troubleshooting Windows installations.

2.9.3. Securing the Initial MySQL Accounts

Part of the MySQL installation process is to set up the `mysql` database containing the grant tables:

- Windows distributions contain preinitialized grant tables that are installed automatically.

- On Unix, the grant tables are populated by the `mysql_install_db` program. Some installation methods run this program for you. Others require that you execute it manually. For details, see Section 2.9.2, "Unix Post-Installation Procedures".

The grant tables define the initial MySQL user accounts and their access privileges. These accounts are set up as follows:

- Two accounts are created with a username of `root`. These are superuser accounts that can do anything. The initial `root` account passwords are empty, so anyone can connect to the MySQL server as `root` *without a password* and be granted all privileges.

  - On Windows, one `root` account is for connecting from the local host and the other allows connections from any host.

  - On Unix, both `root` accounts are for connections from the local host. Connections must be made from the local host by specifying a hostname of `localhost` for one account, or the actual hostname or IP number for the other.

- Two anonymous-user accounts are created, each with an empty username. The anonymous accounts have no passwords, so anyone can use them to connect to the MySQL server.

  - On Windows, one anonymous account is for connections from the local host. It has all privileges, just like the `root` accounts. The other is for connections from any host and has all privileges for the `test` database or other databases with names that start with `test`.

  - On Unix, both anonymous accounts are for connections from the local host. Connections

must be made from the local host by specifying a hostname of localhost for one account, or the actual hostname or IP number for the other. These accounts have all privileges for the test database or other databases with names that start with test_.

As noted, none of the initial accounts have passwords. This means that your MySQL installation is unprotected until you do something about it:

- If you want to prevent clients from connecting as anonymous users without a password, you should either assign passwords to the anonymous accounts or else remove them.

- You should assign passwords to the MySQL root accounts.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the anonymous accounts and then for the root accounts. Replace "*newpwd*" in the examples with the actual password that you want to use. The instructions also cover how to remove the anonymous accounts, should you prefer not to allow anonymous access at all.

You might want to defer setting the passwords until later, so that you don't need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for any real production work.

To assign passwords to the anonymous accounts, you can use either SET PASSWORD or UPDATE. In both cases, be sure to encrypt the password using the PASSWORD() function.

To use SET PASSWORD on Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'%' = PASSWORD('newpwd');
```

To use SET PASSWORD on Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('newpwd');
```

In the second SET PASSWORD statement, replace *host_name* with the name of the server host. This is the name that is specified in the Host column of the non-localhost record for root in the user table. If you don't know what hostname this is, issue the following statement before using SET PASSWORD:

```
mysql> SELECT Host, User FROM mysql.user;
```

Look for the record that has root in the User column and something other than localhost in the Host column. Then use that Host value in the second SET PASSWORD statement.

The other way to assign passwords to the anonymous accounts is by using UPDATE to modify the user table directly. Connect to the server as root and issue an UPDATE statement that assigns a value to the Password column of the appropriate user table records. The procedure is the same for Windows and Unix. The following UPDATE statement assigns a password to both anonymous accounts at once:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
    ->       WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

After you update the passwords in the user table directly using UPDATE, you must tell the server to re-read the grant tables with FLUSH PRIVILEGES. Otherwise, the change goes unnoticed until you restart the server.

If you prefer to remove the anonymous accounts instead, do so as follows:

```
shell> mysql -u root
mysql> DELETE FROM mysql.user WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

The DELETE statement applies both to Windows and to Unix. On Windows, if you want to remove only the anonymous account that has the same privileges as root, do this instead:

```
shell> mysql -u root
mysql> DELETE FROM mysql.user WHERE Host='localhost' AND User='';
mysql> FLUSH PRIVILEGES;
```

This account allows anonymous access but has full privileges, so removing it improves security.

You can assign passwords to the root accounts in several ways. The following discussion demonstrates three methods:

- Use the SET PASSWORD statement

- Use the mysqladmin command-line client program

- Use the UPDATE statement

To assign passwords using SET PASSWORD, connect to the server as root and issue two SET PASSWORD statements. Be sure to encrypt the password using the PASSWORD() function.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'%' = PASSWORD('newpwd');
```

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('newpwd');
```

In the second SET PASSWORD statement, replace *host_name* with the name of the server host. This is the same hostname that you used when you assigned the anonymous account passwords.

To assign passwords to the root accounts using mysqladmin, execute the following commands:

```
shell> mysqladmin -u root password "newpwd"
shell> mysqladmin -u root -h host_name password "newpwd"
```

These commands apply both to Windows and to Unix. In the second command, replace *host_name* with the name of the server host. The double quotes around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

If you are using a server from a *very* old version of MySQL, the mysqladmin commands to set the password fail with the message parse error near 'SET password'. The solution to this problem is to upgrade the server to a newer version of MySQL.

You can also use `UPDATE` to modify the `user` table directly. The following `UPDATE` statement assigns a password to both `root` accounts at once:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
    ->        WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `UPDATE` statement applies both to Windows and to Unix.

After the passwords have been set, you must supply the appropriate password whenever you connect to the server. For example, if you want to use `mysqladmin` to shut down the server, you can do so using this command:

```
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

Note: If you forget your `root` password after setting it up, the procedure for resetting it is covered in Section A.4.1, "How to Reset the Root Password".

To set up new accounts, you can use the `GRANT` statement. For instructions, see Section 5.7.2, "Adding New User Accounts to MySQL".

2.10. Upgrading MySQL

As a general rule, we recommend that when upgrading from one release series to another, you should go to the next series rather than skipping a series. For example, if you currently are running MySQL 3.23 and wish to upgrade to a newer series, upgrade to MySQL 4.0 rather than to 4.1 or 5.0.

The following items form a checklist of things you should do whenever you perform an upgrade:

- Read the upgrading section for the release series to which you are upgrading. Read the change notes as well. These provide information about new features you can use. For example, before upgrading from MySQL 4.1 to 5.0, read the 5.0 upgrading section (see Section 2.10.2, "Upgrading from Version 4.1 to 5.0") and read the 5.0 change notes (see Appendix E, *MySQL Change History*).

- Before you do an upgrade, back up your databases.

- If you are running MySQL Server on Windows, see Section 2.3.15, "Upgrading MySQL on Windows".

- An upgrade may involve changes to the grant tables that are stored in the `mysql` database. Occasionally new columns or tables are added to support new features. To take advantage of these features, be sure that your grant tables are up to date. The upgrade procedure is described in Section 2.10.8, "Upgrading the Grant Tables".

- If you are using replication, see Section 6.6, "Upgrading a Replication Setup" for information on upgrading your replication setup.

- If you install a MySQL-Max distribution that includes a server named `mysqld-max`, then upgrade later to a non-Max version of MySQL, `mysqld_safe` still attempts to run the old `mysqld-max` server. If you perform such an upgrade, you should manually remove the old `mysqld-max` server to ensure that `mysqld_safe` runs the new `mysqld` server.

You can always move the MySQL format files and data files between different versions on the same architecture as long as you stay within versions for the same release series of MySQL. The current production release series is 4.1. If you change the character set when running MySQL, you must run `myisamchk -r -q --set-character-set=charset` on all `MyISAM` tables. Otherwise,

your indexes may not be ordered correctly, because changing the character set may also change the sort order.

Normally you can upgrade MySQL to a newer MySQL version without having to do any changes to your tables. Please confirm if the upgrade notes to the particular version you are upgrading to tells you anything about this. If there would be any incompatibilities you can use `mysqldump` to dump your tables before upgrading. After upgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables.

If you are cautious about using new versions, you can always rename your old `mysqld` before installing a newer one. For example, if you are using MySQL 4.0.18 and want to upgrade to 4.1.1, rename your current server from `mysqld` to `mysqld-4.0.18`. If your new `mysqld` then does something unexpected, you can simply shut it down and restart with your old `mysqld`.

If, after an upgrade, you experience problems with recompiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, you should check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries.

If problems occur, such as that the new `mysqld` server doesn't want to start or that you can't connect without a password, verify that you don't have some old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

It is a good idea to rebuild and reinstall the Perl `DBD::mysql` module whenever you install a new release of MySQL. The same applies to other MySQL interfaces as well, such as the PHP `mysql` extension and the Python `MySQLdb` module.

2.10.1. Upgrading from Version 5.0

When upgrading a 5.0 installation to 5.0.10 or above note that it is *necessary* to run `mysql_fix_privilege_tables` (or the `mysql_fix_privilege_tables.sql` script on Windows). Otherwise, creating stored procedures might not work. The procedure for doing this is described in Section 2.10.8, "Upgrading the Grant Tables".

2.10.2. Upgrading from Version 4.1 to 5.0

Note: Currently, MySQL 5.0 is at Beta status and, as for any other pre-production release, should not be installed on "production" level systems or systems with critical data. It is good practice to back up your data before installing any new version of software. Although MySQL has done its best to ensure a high level of quality, protect your data by making a backup as you would for any software beta release.

In general, you should do the following when upgrading to MySQL 5.0 from 4.1:

- Check the items in the change list found later in this section to see whether any of them might affect your applications. Note particularly any that are marked **Incompatible change**; these result in incompatibilities with earlier versions of MySQL, and may require your attention *before you upgrade*.

- Read the 5.0 news items to see what significant new features you can use in 5.0. See Section E.1, "Changes in release 5.0.x (Development)".

- If you are running MySQL Server on Windows, see Section 2.3.15, "Upgrading MySQL on Windows". Also, two of the Windows MySQL servers were renamed. See Section 2.3.9, "Selecting a MySQL Server type".

- MySQL 5.0 adds support for stored procedures. This support requires the `proc` table in the `mysql` database. To create this file, you should run the `mysql_fix_privilege_tables` script as described in Section 2.10.8, "Upgrading the Grant Tables".

- MySQL 5.0 adds support for views. This support requires extra privilege columns in the `user` and `db` tables in the `mysql` database. To create these columns, you should run the `mysql_fix_privilege_tables` script as described in Section 2.10.8, "Upgrading the Grant Tables".

- If you are using replication, see Section 6.6, "Upgrading a Replication Setup" for information on upgrading your replication setup.

Several visible behaviors have changed between MySQL 4.1 and mySQL 5.0 to make MySQL more compatible with standard SQL. These changes may affect your applications.

The following list describes changes that may affect applications and that you should watch out for when upgrading to version 5.0.

Server Changes:

- **Incompatible change:** The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables has changed. Starting from 5.0.3, `TEXT` indexes are compared as space-padded at the end (just like the way MySQL sorts `CHAR`, `VARCHAR` and `TEXT` fields). If you have a index on a `TEXT` column, you should run `CHECK TABLE` on it. If the check reports errors, rebuild the indexes: Dump and reload the table if it is an `InnoDB` table, or run `OPTIMIZE TABLE` or `REPAIR TABLE` if it is a `MyISAM` table.

- **Incompatible change:** `MyISAM` and `InnoDB` tables created with `DECIMAL` columns in MySQL 5.0.3 to 5.0.5 will appear corrupt after an upgrade to MySQL 5.0.6. Dump such tables with `mysqldump` before upgrading, and then reload them after upgrading. (The same incompatibility will occur for these tables created in MySQL 5.0.6 after a downgrade to MySQL 5.0.3 to 5.0.5.)

- **Incompatible change:** As of MySQL 5.0.3, the server by default no longer loads user-defined functions unless they have at least one auxiliary symbol (for example, an `xxx_init` or `xxx_deinit` symbol) defined in addition to the main function symbol. This behavior can be overridden with the `--allow-suspicious-udfs` option. See Section 25.2.3.6, "User-defined Function Security Precautions".

- **Incompatible change:** The update log is removed, so if you enabled it in the past, you should enable the binary log instead. See Section E.1, "Changes in release 5.0.x (Development)".

- **Incompatible change:** Support for the `ISAM` storage engine has been removed. If you have `ISAM` tables, you should convert them before upgrading. For example, to convert an `ISAM` table to use the `MyISAM` storage engine, use this statement:

```
ALTER TABLE tbl_name ENGINE = MyISAM;
```

Use a similar statement for each `ISAM` table.

- **Incompatible change:** Support for `RAID` options in `MyISAM` tables has been removed. If you have tables that use these options, you should convert them before upgrading. One way to do this is to dump them with `mysqldump`, edit the dump file to remove the `RAID` options in the `CREATE TABLE` statements, and reload the dump file. Another possibility is to use `CREATE TABLE new_tbl ... SELECT raid_tbl` to create a new table from the `RAID` table. However, the `CREATE TABLE` part of the statement must contain sufficient information to recreate column attributes as well as indexes, or column attributes may be lost and indexes will not appear in the new table. See Section 13.1.5, "CREATE TABLE Syntax".

  The `.MYD` files for `RAID` tables in a given database are stored under the database directory in subdirectories that have names consisting of two hex digits in the range from `00` to `ff`. After converting all tables that use `RAID` options, these `RAID`-related subdirectories still will exist but can be removed. Verify that they are empty, and then remove them manually. (If they are not empty, there is some `RAID` table that has not been converted.)

- In MySQL 5.0.6, binary logging of stored routines and triggers was changed. This change has implications for security, replication, and data recovery, as discussed in Section 18.4, "Binary Logging of Stored Routines and Triggers".

SQL Changes:

- `DECIMAL` columns now are stored in a more efficient format. To convert a table to use the new `DECIMAL` type, you should do an `ALTER TABLE` on it. The `ALTER TABLE` also will change the table's `VARCHAR` columns to use the new `VARCHAR` column type. For information about possible incompatibilities with old applications, see Chapter 22, *Precision Math*.

- MySQL 5.0.3 and up uses precision math when calculating with `DECIMAL` values (64 decimal digits) and for rounding exact-value numbers. See Chapter 22, *Precision Math*.

- As of MySQL 5.0.3, trailing spaces no longer are removed from values stored in `VARCHAR` and `VARBINARY` columns. The maximum length for `VARCHAR` or `VARBINARY` now is 65,535 characters or bytes, respectively.

  Note: If you create a table with new `VARCHAR` or `VARBINARY` columns in MySQL 5.0.3 or up, the table will not be usable if you downgrade to a version older than 5.0.3. Dump the table before downgrading and then reload it after downgrading.

- As of MySQL 5.0.3, `BIT` is a separate data type, not a synonym for `TINYINT(1)`. See Section 11.1.1, "Overview of Numeric Types".

- MySQL 5.0.2 adds several SQL modes that allow stricter control over rejecting records that have invalid or missing values. See Section 5.3.2, "The Server SQL Mode". See Section 1.8.6.2, "Constraints on Invalid Data". If you want to enable this control but continue to use MySQL's capability for storing incorrect dates such as `'2004-02-31'`, you should start the server with `--sql_mode=TRADITIONAL,ALLOW_INVALID_DATES`.

- As of MySQL 5.0.2, the `SCHEMA` and `SCHEMAS` keywords are accepted as synonyms for `DATABASE` and `DATABASES`.

- User variables are not case sensitive. In MySQL 4.1, `SET @x = 0; SET @X = 1; SELECT @x;` creates two variables and returns 0. In MySQL 5.0, it creates one variable and returns 1.

C API Changes:

- The `reconnect` flag in the `MYSQL` structure is set to 0 by `mysql_real_connect()`. Only those client programs which didn't explicitly set this flag to 0 or 1 after `mysql_real_connect()` experience a change. Having automatic reconnection enabled by default was considered too dangerous (after reconnection, table locks, temporary tables, user and session variables are lost).

2.10.3. Upgrading from Version 4.0 to 4.1

In general, you should do the following when upgrading to MySQL 4.1 from 4.0:

- Check the items in the change list found later in this section to see whether any of them might affect your applications. Note particularly any that are marked **Incompatible change**; these result in incompatibilities with earlier versions of MySQL and you should consider the implications of these incompatibilities *before you upgrade*. Note particularly the items under "Server Changes" that related to changes in character set support.

- Read the 4.1 news items to see what significant new features you can use in 4.1. See Sec-

tion E.2, "Changes in release 4.1.x (Production)".

- If you are running MySQL Server on Windows, see Section 2.3.15, "Upgrading MySQL on Windows".

- After upgrading, update the grant tables to have the new longer `Password` column that is needed for more secure handling of passwords. The procedure uses `mysql_fix_privilege_tables` and is described in Section 2.10.8, "Upgrading the Grant Tables". If you don't do this, MySQL does not use the new more secure protocol to authenticate. Implications of the password-handling change for applications are given later in this section.

- If you are using replication, see Section 6.6, "Upgrading a Replication Setup" for information on upgrading your replication setup.

- The Berkeley DB table handler is updated to DB 4.1 (from 3.2) which has a new log format. If you have to downgrade back to 4.0 you must use `mysqldump` to dump your `BDB` tables in text format and delete all `log.XXXXXXXXXX` files before you start MySQL 4.0 and reload the data.

- MySQL 4.1.3 introduces support for per-connection time zones. See Section 5.9.8, "MySQL Server Time Zone Support". To enable recognition of named time zones, you should create the time zone tables in the `mysql` database. For instructions, see Section 2.9, "Post-Installation Setup and Testing".

- If you are using an old `DBD-mysql` module (`Msql-MySQL-modules`) you have to upgrade to use the newer `DBD-mysql` module. Anything above `DBD-mysql` 2.xx should be fine.

  If you don't upgrade, some methods (such as `DBI->do()`) do not notice error conditions correctly.

- The `--defaults-file=option_file_name` option gives an error if the option file doesn't exist.

- Some notes about upgrading from MySQL 4.0 to MySQL 4.1 on Netware: Make sure to upgrade Perl and PHP versions. Download Perl 5 for Netware from http://forge.novell.com/modules/xfmod/project/?perl5 and PHP from http://forge.novell.com/modules/xfmod/project/?php. Download and install Perl module for MySQL 4.1 from http://forge.novell.com/modules/xfmod/project/showfiles.php?group_id=1126 and PHP Extension for MySQL 4.1 from http://forge.novell.com/modules/xfmod/project/showfiles.php?group_id=1078.

Several visible behaviors have changed between MySQL 4.0 and MySQL 4.1 to fix some critical bugs and make MySQL more compatible with standard SQL. These changes may affect your applications.

Some of the 4.1 behaviors can be tested in 4.0 before performing a full upgrade to 4.1. We have added to later MySQL 4.0 releases (from 4.0.12 on) a `--new` startup option for `mysqld`. See Section 5.3.1, "`mysqld` Command-Line Options".

This option gives you the 4.1 behavior for the most critical changes. You can also enable these behaviors for a given client connection with the `SET @@new=1` command, or turn them off if they are on with `SET @@new=0`.

If you believe that some of the 4.1 changes affect you, we recommend that before upgrading to 4.1, you download the latest MySQL 4.0 version and run it with the `--new` option by adding the following to your config file:

```
[mysqld-4.0]
new
```

That way you can test the new behaviors in 4.0 to make sure that your applications work with them. This helps you have a smooth, painless transition when you perform a full upgrade to 4.1 later. Putting the `--new` option in the `[mysqld-4.0]` option group ensures that you don't accidentally

later run the 4.1 version with the `--new` option.

The following lists describe changes that may affect applications and that you should watch out for when upgrading to version 4.1.

Server Changes:

The most notable change is that character set support has been improved. The server supports multiple character sets, and all tables and non-binary string columns (CHAR, VARCHAR, and TEXT) have a character set. See Chapter 10, *Character Set Support*. Binary string columns (BINARY, VARBINARY, and BLOB) contain strings of bytes and do not have a character set. **Note**: This change in character set support results in the potential for table damage if you do not upgrade properly, so consider carefully the incompatibilities noted here.

- **Incompatible change:** There are conditions under which you should rebuild tables. In general, to rebuild a table, dump it with `mysqldump` and reload the dump file. Some items in the following list indicate alternatives means for rebuilding.

  - If you have created or used `InnoDB` tables with `TIMESTAMP` columns in MySQL versions 4.1.0 to 4.1.3, you have to rebuild those tables when you upgrade to MySQL 4.1.4 or later. The storage format in those MySQL versions for a `TIMESTAMP` column was incorrect. If you upgrade from MySQL 4.0 to 4.1.4 or later, then no rebuild of tables with `TIMESTAMP` columns is needed.

  - Starting from MySQL 4.1.3, `InnoDB` uses the same character set comparison functions as MySQL for non-latin1_swedish_ci character strings that are not `BINARY`. This changes the sorting order of space and characters with a code < ASCII(32) in those character sets. For `latin1_swedish_ci` character strings and `BINARY` strings, `InnoDB` uses its own pad-spaces-at-end comparison method, which stays unchanged. Note that `latin1_swedish_ci` is the default collation order for `latin1` in 4.0. If you have an InnoDB table created with MySQL 4.1.2 or earlier, with an index on a non-latin1_swedish_ci character set and collation order column that is not `BINARY` (in the case of 4.1.0 and 4.1.1, with any character set and collation), and that column may contain characters with a code < ASCII(32), then you should do `ALTER TABLE` or `OPTIMIZE TABLE` on it to regenerate the index, after upgrading to MySQL 4.1.3 or later. You can also rebuild the table from a dump.

    `MyISAM` tables also have to be rebuilt or repaired in these cases. You can use `mysqldump` to dump them in 4.0 and then reload them in 4.1. An alternative is to use `OPTIMIZE TABLE` after upgrading, but this *must* be done before any updates are made in 4.1.

  - If you have used column prefix indexes on UTF8 columns or other multi-byte character set columns in MySQL 4.1.0 to 4.1.5, you must rebuild the tables when you upgrade to MySQL 4.1.6 or later.

  - If you have used accent characters (characters with byte values of 128 to 255) in database names, table names, constraint names, or column names in versions of MySQL earlier than 4.1, you cannot upgrade to MySQL 4.1 directly, because 4.1 uses UTF8 to store metadata names. Use `RENAME TABLE` to overcome this if the accent character is in the table name or the database name, or rebuild the table.

  - String comparison works according to SQL standard: Instead of stripping end spaces before comparison, we now extend the shorter string with spaces. The problem with this is that now `'a' > 'a\t'`, which it wasn't before. If you have any tables where you have an indexed CHAR, VARCHAR or TEXT column in which the last character in the index may be less than ASCII(32), you should use `REPAIR TABLE` or `mysqlcheck` to ensure that the table is correct.

  - `MyISAM` tables now use a better checksum algorithm. If you have `MyISAM` tables with live checksum enabled (you used CHECKSUM=1 in `CREATE TABLE` or `ALTER TABLE`), these tables will appear corrupted. Use `REPAIR TABLE` to recalculate the checksum.

- **Incompatible change:** MySQL interprets length specifications in character column definitions

in characters. (Earlier versions interpret them in bytes.) For example, `CHAR(N)` means *N* characters, not *N* bytes.

For single-byte character sets, this change makes no difference. However, if you upgrade to MySQL 4.1 and configure the server to use a multi-byte character set, the apparent length of character columns changes. Suppose that a 4.0 table contains a `CHAR(8)` column used to store `ujis` characters. Eight bytes can store from two to four `ujis` characters. If you upgrade to 4.1 and configure the server to use `ujis` as its default character set, the server interprets character column lengths based on the maximum size of a `ujis` character, which is three bytes. The number of three-byte characters that fit in eight bytes is two. Consequently, if you use `SHOW CRE-ATE TABLE` to view the table definition, MySQL displays `CHAR(2)`. You can retrieve existing data from the table, but you can only store new values containing up to two characters. To correct this issue, use `ALTER TABLE` to change the column definition. For example:

```
ALTER TABLE tbl_name MODIFY col_name CHAR(8);
```

- **Important note:** MySQL 4.1 stores table names and column names in `UTF8`. If you have table names or column names that use characters outside of the standard 7-bit US-ASCII range, you may have to do a `mysqldump` of your tables in MySQL 4.0 and restore them after upgrading to MySQL 4.1. The symptom for this problem is that you get a `table not found` error when trying to access your tables. In this case, you should be able to downgrade back to MySQL 4.0 and access your data.

- **Important note:** If you upgrade to MySQL 4.1.1 or higher, it is difficult to downgrade back to 4.0 or 4.1.0! That is because, for earlier versions, `InnoDB` is not aware of multiple tablespaces.

- **Incompatible change:** In connection with the support for per-connection time zones in MySQL 4.1.3, the `timezone` system variable was renamed to `system_time_zone`.

- All tables and non-binary string columns (`CHAR`, `VARCHAR`, and `TEXT`) have a character set. See Chapter 10, *Character Set Support*. Binary string columns (`BINARY`, `VARBINARY`, and `BLOB`) contain strings of bytes and do not have a character set.

  Character set information is displayed by `SHOW CREATE TABLE` and `mysqldump`. (MySQL versions 4.0.6 and above can read the new dump files; older versions cannot.) This change should not affect applications that use only one character set.

- If you were using columns with the `CHAR BINARY` or `VARCHAR BINARY` data types in MySQL 4.0, these were treated as binary strings. To have them treated as binary strings in MySQL 4.1, you should convert them to use the `BINARY` and `VARBINARY` data types, respectively.

- If you have table columns that store character data represented in a character set that the 4.1 server supports directly, you can convert the columns to the proper character set using the instructions in Section 10.10.2, "Converting 4.0 Character Columns to 4.1 Format". Also, database, table, and column identifiers are stored internally using Unicode (UTF8) regardless of the default character set. See Section 9.2, "Database, Table, Index, Column, and Alias Names".

- The table definition format used in `.frm` files has changed slightly in 4.1. MySQL 4.0 versions from 4.0.11 on can read the new `.frm` format directly, but older versions cannot. If you need to move tables from 4.1 to a version earlier than 4.0.11, you should use `mysqldump`. See Section 8.8, "mysqldump — A Database Backup Program".

- Windows servers support connections from local clients using shared memory if run with the `--shared-memory` option. If you are running multiple servers this way on the same Windows machine, you should use a different `--shared-memory-base-name` option for each server.

- **Incompatible change:** The interface to aggregate user-defined functions has changed a bit as of MySQL 4.1.1. You must declare a `xxx_clear()` function for each aggregate function `XXX()`. `xxx_clear()` is used instead of `xxx_reset()`. See Section 25.2.3.2, "UDF Calling Sequences for aggregate functions".

- As of MySQL 4.1.10a, the server by default no longer loads user-defined functions unless they have at least one auxiliary symbol defined in addition to the main function symbol. This behavior can be overridden with the `--allow-suspicious-udfs` option. See Section 25.2.3.6, "User-defined Function Security Precautions".

- A new startup option named `innodb_table_locks` was added that causes `LOCK TABLE` to also acquire InnoDB table locks. This option is enabled by default. This can cause deadlocks in applications that use `AUTOCOMMIT=1` and `LOCK TABLES`. If you application encounters deadlocks after upgrading, you may need to add `innodb_table_locks=0` to your `my.cnf` file.

Client Changes:

- `mysqldump` has the `--opt` and `--quote-names` options enabled by default. You can turn them off with `--skip-opt` and `--skip-quote-names`.

SQL Changes:

- **Incompatible change:** String comparison works according to SQL standard: Instead of stripping end spaces before comparison, we now extend the shorter string with spaces. The problem with this is that now `'a' > 'a\t'`, which it wasn't before. If you have any tables where you have an indexed `CHAR`, `VARCHAR` or `TEXT` column in which the last character in the index may be less than `ASCII(32)`, you should use `REPAIR TABLE` or `mysqlcheck` to ensure that the table is correct.

- **Incompatible change:** `TIMESTAMP` is returned as a string in `'YYYY-MM-DD HH:MM:SS'` format. See Section 11.3.1.2, "`TIMESTAMP` Properties as of MySQL 4.1". From 4.0.12 on, the `--new` option can be used to make a 4.0 server behave as 4.1 in this respect. The effect of this option is described in Section 11.3.1.1, "`TIMESTAMP` Properties Prior to MySQL 4.1".

  When running the server with `--new`, if you want to have a `TIMESTAMP` column returned as a number (as MySQL 4.0 does by default), you should add `+0` when you retrieve it:

  ```
  mysql> SELECT ts_col + 0 FROM tbl_name;
  ```

  Display widths for `TIMESTAMP` columns are no longer supported. For example, if you declare a column as `TIMESTAMP(10)`, the `(10)` is ignored.

  These changes were necessary for SQL standards compliance. In a future version, a further change will be made (backward compatible with this change), allowing the timestamp length to indicate the desired number of digits for fractions of a second.

- **Incompatible change:** Binary values such as `0xFFDF` are assumed to be strings instead of numbers. This fixes some problems with character sets where it's convenient to input a string as a binary value. With this change, you should use `CAST()` if you want to compare binary values numerically as integers:

  ```
  mysql> SELECT CAST(0xFEFF AS UNSIGNED INTEGER)
      ->           < CAST(0xFF AS UNSIGNED INTEGER);
          -> 0
  ```

  If you don't use `CAST()`, a lexical string comparison is done:

  ```
  mysql> SELECT 0xFEFF < 0xFF;
          -> 1
  ```

  Using binary items in a numeric context or comparing them using the = operator should work as before. (The `--new` option can be used from 4.0.13 on to make a 4.0 server behave as 4.1 in this respect.)

- **Incompatible change:** Before MySQL 4.1.1, the statement parser was less strict and its string-to-date conversion would ignore everything up to the first digit. As a result, invalid statements such as the following were accepted:

```
INSERT INTO t (datetime_col) VALUES ('stuff 2005-02-11 10:17:01');
```

As of MySQL 4.1.1, the parser is more strict and treats the string as an invalid date, so the preceding statement results in a warning.

- **Incompatible change:** In MySQL 4.1.2, the `Type` column in the output from `SHOW TABLE STATUS` was renamed to `Engine`. This affects applications that identify output columns by name rather than by position.

- When using multiple-table `DELETE` statements, you should use the alias of the tables from which you want to delete, not the actual table name. For example, instead of doing this:

```
DELETE test FROM test AS t1, test2 WHERE ...
```

Do this:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

This corrects a problem that was present in MySQL 4.0.

- For functions that produce a `DATE`, `DATETIME`, or `TIME` value, the result returned to the client is fixed up to have a temporal type. For example, in MySQL 4.1, you get this result:

```
mysql> SELECT CAST('2001-1-1' AS DATETIME);
        -> '2001-01-01 00:00:00'
```

In MySQL 4.0, the result is different:

```
mysql> SELECT CAST('2001-1-1' AS DATETIME);
        -> '2001-01-01'
```

- `DEFAULT` values no longer can be specified for `AUTO_INCREMENT` columns. (In 4.0, a `DEFAULT` value is silently ignored; in 4.1, an error occurs.)

- `LIMIT` no longer accepts negative arguments. Use some large number (maximum 18446744073709551615) instead of -1.

- `SERIALIZE` is no longer a valid mode value for the `sql_mode` variable. You should use `SET TRANSACTION ISOLATION LEVEL SERIALIZABLE` instead. `SERIALIZE` is no longer valid for the `--sql-mode` option for `mysqld`, either. Use `--transaction-isolation=SERIALIZABLE` instead.

C API Changes:

- **Incompatible change:** The `mysql_shutdown()` C API function has an extra parameter as of MySQL 4.1.3: SHUTDOWN-level. You should convert any `mysql_shutdown(X)` call you have in your application to `mysql_shutdown(X,SHUTDOWN_DEFAULT)`. Any third-party API that links against the C API library must be modified to account for this change or it will not compile.

- Some C API calls such as `mysql_real_query()` return `1` on error, not `-1`. You may have to change some old applications if they use constructs like this:

```
if (mysql_real_query(mysql_object, query, query_length) == -1)
```

```
{
  printf("Got error");
}
```

Change the call to test for a non-zero value instead:

```
if (mysql_real_query(mysql_object, query, query_length) != 0)
{
  printf("Got error");
}
```

Password-Handling Changes:

The password hashing mechanism has changed in 4.1 to provide better security, but this may cause compatibility problems if you still have clients that use the client library from 4.0 or earlier. (It is very likely that you have 4.0 clients in situations where clients connect from remote hosts that have not yet upgraded to 4.1.) The following list indicates some possible upgrade strategies. They represent various tradeoffs between the goal of compatibility with old clients and the goal of security.

- Only upgrade the client to use 4.1 client libraries (not the server). No behavior changes (except the return value of some API calls), but you cannot use any of the new features provided by the 4.1 client/server protocol, either. (MySQL 4.1 has an extended client/server protocol that offers such features as prepared statements and multiple result sets.) See Section 23.2.4, "C API Prepared Statements".

- Upgrade to 4.1 and run the `mysql_fix_privilege_tables` script to widen the `Password` column in the `user` table so that it can hold long password hashes. But run the server with the `--old-passwords` option to provide backward compatibility that allows pre-4.1 clients to continue to connect to their short-hash accounts. Eventually, when all your clients are upgraded to 4.1, you can stop using the `--old-passwords` server option. You can also change the passwords for your MySQL accounts to use the new more secure format. A pure-4.1 installation is the most secure.

Further background on password hashing with respect to client authentication and password-changing operations may be found in Section 5.6.9, "Password Hashing in MySQL 4.1" and Section A.2.3, "`Client does not support authentication protocol`".

2.10.4. Upgrading from Version 3.23 to 4.0

In general, you should do the following when upgrading to MySQL 4.0 from 3.23:

- Check the items in the change list found later in this section to see whether any of them might affect your applications. Note particularly any that are marked **Incompatible change**; these result in incompatibilities with earlier versions of MySQL.

- Read the 4.0 news items to see what significant new features you can use in 4.0. See Section E.3, "Changes in release 4.0.x (Production)".

- If you are running MySQL Server on Windows, see Section 2.3.15, "Upgrading MySQL on Windows".

- After upgrading, update the grant tables to add new privileges and features. The procedure uses the `mysql_fix_privilege_tables` script and is described in Section 2.10.8, "Upgrading the Grant Tables".

- If you are using replication, see Section 6.6, "Upgrading a Replication Setup" for information on upgrading your replication setup.

- Edit any MySQL startup scripts or option files to not use any of the deprecated options described later in this section.

- Convert your old `ISAM` files to `MyISAM` files. One way to do this is with the `mysql_convert_table_format` script. (This is a Perl script; it requires that DBI be installed.) To convert the tables in a given database, use this command:

  shell> **mysql_convert_table_format database *db_name***

  Note that this should be used only if all tables in the given database are `ISAM` or `MyISAM` tables. To avoid converting tables of other types to `MyISAM`, you can explicitly list the names of your `ISAM` tables after the database name on the command line.

  Individual tables can be changed to `MyISAM` by using the following `ALTER TABLE` statement for each table to be converted:

  mysql> **ALTER TABLE *tbl_name* TYPE=MyISAM;**

  If you are not sure of the table type for a given table, use this statement:

  mysql> **SHOW TABLE STATUS LIKE '*tbl_name*';**

- Ensure that you don't have any MySQL clients that use shared libraries (like the Perl `DBD::mysql` module). If you do, you should recompile them, because the data structures used in `libmysqlclient.so` have changed. The same applies to other MySQL interfaces as well, such as the Python `MySQLdb` module.

MySQL 4.0 works even if you don't perform the preceding actions, but you cannot use the new security privileges in MySQL 4.0 and you may run into problems when upgrading later to MySQL 4.1 or newer. The `ISAM` file format still works in MySQL 4.0, but is deprecated and is not compiled in by default as of MySQL 4.1. `MyISAM` tables should be used instead.

Old clients should work with a MySQL 4.0 server without any problems.

Even if you perform the preceding actions, you can still downgrade to MySQL 3.23.52 or newer if you run into problems with the MySQL 4.0 series. In this case, you must use `mysqldump` to dump any tables that use full-text indexes and reload the dump file into the 3.23 server. This is necessary because 4.0 uses a new format for full-text indexing.

The following lists describe changes that may affect applications and that you should watch out for when upgrading to version 4.0.

Server Changes:

- As of MySQL 4.0.24, the server by default no longer loads user-defined functions unless they have at least one auxiliary symbol defined in addition to the main function symbol. This behavior can be overridden with the `--allow-suspicious-udfs` option. See Section 25.2.3.6, "User-defined Function Security Precautions".

- MySQL 4.0 has a lot of new privileges in the `mysql.user` table. See Section 5.6.3, "Privileges Provided by MySQL".

  To get these new privileges to work, you must update the grant tables. The procedure is described in Section 2.10.8, "Upgrading the Grant Tables". Until you do this, all accounts have the `SHOW DATABASES`, `CREATE TEMPORARY TABLES`, and `LOCK TABLES` privileges. `SUPER` and `EXECUTE` privileges take their value from `PROCESS`. `REPLICATION SLAVE` and `REPLICATION CLIENT` take their values from `FILE`.

  If you have any scripts that create new MySQL user accounts, you may want to change them to

use the new privileges. If you are not using GRANT commands in the scripts, this is a good time to change your scripts to use GRANT instead of modifying the grant tables directly.

From version 4.0.2 on, the option --safe-show-database is deprecated (and no longer does anything). See Section 5.5.3, "Startup Options for mysqld Concerning Security".

If you get Access denied errors for new users in version 4.0.2 and up, you should check whether you need some of the new grants that you didn't need before. In particular, you need REPLICATION SLAVE (instead of FILE) for new slave servers.

- safe_mysqld has been renamed to mysqld_safe. For backward compatibility, binary distributions will for some time include safe_mysqld as a symlink to mysqld_safe.

- InnoDB support is included by default in binary distributions. If you build MySQL from source, InnoDB is configured in by default. If you do not use InnoDB and want to save memory when running a server that has InnoDB support enabled, use the --skip-innodb server startup option. To compile MySQL without InnoDB support, run configure with the --without-innodb option.

- Values for the startup parameters myisam_max_extra_sort_file_size and myisam_max_extra_sort_file_size are given in bytes (they were given in megabytes before 4.0.3).

- mysqld has the option --temp-pool enabled by default because this gives better performance with some operating systems (most notably Linux).

- The mysqld startup options --skip-locking and --enable-locking were renamed to --skip-external-locking and --external-locking.

- External system locking of MyISAM/ISAM files is turned off by default. You can turn this on with --external-locking. (However, this is never needed for most users.)

- The following startup variables and options have been renamed:

Old Name	New Name
myisam_bulk_insert_tree_size	bulk_insert_buffer_size
query_cache_startup_type	query_cache_type
record_buffer	read_buffer_size
record_rnd_buffer	read_rnd_buffer_size
sort_buffer	sort_buffer_size
warnings	log-warnings
--err-log	--log-error (for mysqld_safe)

The startup options record_buffer, sort_buffer, and warnings still work in MySQL 4.0 but are deprecated.

SQL Changes:

- The following SQL variables have been renamed:

Old Name	New Name
SQL_BIG_TABLES	BIG_TABLES
SQL_LOW_PRIORITY_UPDATES	LOW_PRIORITY_UPDATES
SQL_MAX_JOIN_SIZE	MAX_JOIN_SIZE
SQL_QUERY_CACHE_TYPE	QUERY_CACHE_TYPE

The old names still work in MySQL 4.0 but are deprecated.

- You have to use SET GLOBAL SQL_SLAVE_SKIP_COUNTER=skip_count instead of SET SQL_SLAVE_SKIP_COUNTER=skip_count.

- SHOW MASTER STATUS returns an empty set if binary logging is not enabled.

- SHOW SLAVE STATUS returns an empty set if the slave is not initialized.

- SHOW INDEX has two more columns than it had in 3.23 (Null and Index_type).

- The format of SHOW OPEN TABLES has changed.

- ORDER BY col_name DESC sorts NULL values last, as of MySQL 4.0.11. In 3.23 and in earlier 4.0 versions, this was not always consistent.

- CHECK, LOCALTIME, and LOCALTIMESTAMP are reserved words.

- DOUBLE and FLOAT columns honor the UNSIGNED flag on storage (before, UNSIGNED was ignored for these columns).

- The result of all bitwise operators (|, &, <<, >>, and ~) is unsigned. This may cause problems if you are using them in a context where you want a signed result. See Section 12.8, "Cast Functions and Operators".

  Note: When you use subtraction between integer values where one is of type UNSIGNED, the result is unsigned. In other words, before upgrading to MySQL 4.0, you should check your application for cases in which you are subtracting a value from an unsigned entity and want a negative answer or subtracting an unsigned value from an integer column. You can disable this behavior by using the --sql-mode=NO_UNSIGNED_SUBTRACTION option when starting mysqld. See Section 5.3.2, "The Server SQL Mode".

- You should use integers to store values in BIGINT columns (instead of using strings, as you did in MySQL 3.23). Using strings still works, but using integers is more efficient.

- In MySQL 3.23, INSERT INTO ... SELECT always had IGNORE enabled. As of 4.0.1, MySQL stops (and possibly rolls back) by default in case of an error unless you specify IG-NORE.

- You should use TRUNCATE TABLE when you want to delete all rows from a table and you don't need to obtain a count of the number of rows that were deleted. (DELETE FROM tbl_name returns a row count in 4.0 and doesn't reset the AUTO_INCREMENT counter, and TRUNCATE TABLE is faster.)

- You get an error if you have an active transaction or LOCK TABLES statement when trying to execute TRUNCATE TABLE or DROP DATABASE.

- To use MATCH ... AGAINST (... IN BOOLEAN MODE) full-text searches with your tables, you must rebuild their indexes with REPAIR TABLE tbl_name USE_FRM. If you attempt a boolean full-text search without rebuilding the indexes this way, the search returns incorrect results. See Section 12.7.4, "Fine-Tuning MySQL Full-Text Search".

- LOCATE() and INSTR() are case sensitive if one of the arguments is a binary string. Otherwise they are case insensitive.

- STRCMP() uses the current character set when performing comparisons. This makes the default comparison behavior not case sensitive unless one or both of the operands are binary strings.

- HEX(str) returns the characters in str converted to hexadecimal. If you want to convert a number to hexadecimal, you should ensure that you call HEX() with a numeric argument.

- RAND(seed) returns a different random number series in 4.0 than in 3.23; this was done to further differentiate RAND(seed) and RAND(seed+1).

- The default type returned by IFNULL(A,B) is set to be the more "general" of the types of A and B. (The general-to-specific order is string, REAL, INTEGER).

C API Changes:

- The old C API functions mysql_drop_db(), mysql_create_db(), and mysql_connect() are no longer supported unless you compile MySQL with CFLAGS=-DUSE_OLD_FUNCTIONS. However, it is preferable to change client programs to use the new 4.0 API instead.

- In the MYSQL_FIELD structure, length and max_length have changed from unsigned int to unsigned long. This should not cause any problems, except that they may generate warning messages when used as arguments in the printf() class of functions.

- Multi-threaded clients should use mysql_thread_init() and mysql_thread_end(). See Section 23.2.15, "How to Make a Threaded Client".

Other Changes:

- If you want to recompile the Perl DBD::mysql module, use a recent version. Version 2.9003 is recommended. Versions older than 1.2218 should not be used because they use the deprecated mysql_drop_db() call.

2.10.5. Upgrading from Version 3.22 to 3.23

MySQL 3.22 and 3.21 clients work without any problems with a MySQL 3.23 server.

When upgrading to MySQL 3.23 from an earlier version, note the following changes:

Table Changes:

- MySQL 3.23 supports tables of the new MyISAM type and the old ISAM type. By default, all new tables are created with type MyISAM unless you start mysqld with the --default-table-type=isam option. You don't have to convert your old ISAM tables to use them with MySQL 3.23. You can convert an ISAM table to MyISAM format with ALTER TABLE *tbl_name* TYPE=MyISAM or the Perl script mysql_convert_table_format.

- All tables that use the tis620 character set must be fixed with myisamchk -r or REPAIR TABLE.

- If you are using the german character sort order for ISAM tables, you must repair them with isamchk -r, because we have made some changes in the sort order.

Client Program Changes:

- The MySQL client mysql is by default started with the --no-named-commands (-g) option. This option can be disabled with --enable-named-commands (-G). This may cause incompatibility problems in some cases---for example, in SQL scripts that use named commands without a semicolon. Long format commands still work from the first line.

- If you want your mysqldump files to be compatible between MySQL 3.22 and 3.23, you should not use the --opt or --all option to mysqldump.

SQL Changes:

- If you do a `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted. This didn't happen in MySQL 3.22 because `configure` didn't detect the availability of the `readlink()` system call.

- `OPTIMIZE TABLE` works only for `MyISAM` tables. For other table types, you can use `ALTER TABLE` to optimize the table. During `OPTIMIZE TABLE`, the table is locked to prevent it from being used by other threads.

- Date functions that work on parts of dates (such as `MONTH()`) return 0 for `0000-00-00` dates. In MySQL 3.22, these functions returned `NULL`.

- The default return type of `IF()` depends on both arguments, not just the first one.

- `AUTO_INCREMENT` columns should not be used to store negative numbers. The reason for this is that negative numbers caused problems when wrapping from -1 to 0. You should not store 0 in `AUTO_INCREMENT` columns, either; `CHECK TABLE` complains about 0 values because they may change if you dump and restore the table. `AUTO_INCREMENT` for `MyISAM` tables is handled at a lower level and is much faster than before. In addition, for `MyISAM` tables, old numbers are not reused, even if you delete rows from the table.

- `CASE`, `DELAYED`, `ELSE`, `END`, `FULLTEXT`, `INNER`, `RIGHT`, `THEN`, and `WHEN` are reserved words.

- `FLOAT(p)` is a true floating-point type and not a value with a fixed number of decimals.

- When declaring columns using a `DECIMAL(length,dec)` type, the `length` argument no longer includes a place for the sign or the decimal point.

- A `TIME` string must be of one of the following formats: `[[[DAYS] [H]H:]MM:]SS[.fraction]` or `[[[[[H]H]H]H]MM]SS[.fraction]`.

- `LIKE` compares strings using the same character comparison rules as for the = operator. If you require the old behavior, you can compile MySQL with the `CXXFLAGS=-DLIKE_CMP_TOUPPER` flag.

- `REGEXP` is case insensitive if neither of the strings is a binary string.

- When you check or repair `MyISAM` (`.MYI`) tables, you should use the `CHECK TABLE` statement or the `myisamchk` command. For `ISAM` (`.ISM`) tables, use the `isamchk` command.

- Check all your calls to `DATE_FORMAT()` to make sure that there is a '`%`' before each format character.

- In MySQL 3.22, the output of `SELECT DISTINCT ...` was almost always sorted. In MySQL 3.23, you must use `GROUP BY` or `ORDER BY` to obtain sorted output.

- `SUM()` returns `NULL` instead of 0 if there are no matching rows. This is required by standard SQL.

- An `AND` or `OR` with `NULL` values returns `NULL` instead of 0. This mostly affects queries that use `NOT` on an `AND`/`OR` expression as `NOT NULL = NULL`.

- `LPAD()` and `RPAD()` shorten the result string if it's longer than the length argument.

C API Changes:

- `mysql_fetch_fields_direct()` is a function instead of a macro. It returns a pointer to a `MYSQL_FIELD` instead of a `MYSQL_FIELD`.

- `mysql_num_fields()` cannot be used on a `MYSQL*` object (it's a function that takes a `MYSQL_RES*` value as an argument). With a `MYSQL*` object, you should use `mysql_field_count()` instead.

2.10.6. Upgrading from Version 3.21 to 3.22

Nothing that affects compatibility has changed between versions 3.21 and 3.22. The only pitfall is that new tables that are created with `DATE` type columns use the new way to store the date. You can't access these new columns from an old version of `mysqld`.

When upgrading to MySQL 3.23 from an earlier version, note the following changes:

- After installing MySQL Version 3.22, you should start the new server and then run the `mysql_fix_privilege_tables` script. This adds the new privileges that you need to use the `GRANT` command. If you forget this, you get `Access denied` when you try to use `ALTER TABLE`, `CREATE INDEX`, or `DROP INDEX`. The procedure for updating the grant tables is described in Section 2.10.8, "Upgrading the Grant Tables".

- The C API interface to `mysql_real_connect()` has changed. If you have an old client program that calls this function, you must pass a `0` for the new `db` argument (or recode the client to send the `db` element for faster connections). You must also call `mysql_init()` before calling `mysql_real_connect()`. This change was done to allow the new `mysql_options()` function to save options in the `MYSQL` handler structure.

- The `mysqld` variable `key_buffer` has been renamed to `key_buffer_size`, but you can still use the old name in your startup files.

2.10.7. Upgrading from Version 3.20 to 3.21

If you are running a version older than Version 3.20.28 and want to switch to Version 3.21, you need to do the following:

You can start the `mysqld` Version 3.21 server with the `--old-protocol` option to use it with clients from a Version 3.20 distribution. In this case, the server uses the old pre-3.21 `password()` checking rather than the new method. Also, the new client function `mysql_errno()` does not return any server error, only `CR_UNKNOWN_ERROR`. The function does work for client errors.

If you are *not* using the `--old-protocol` option to `mysqld`, you need to make the following changes:

- All client code must be recompiled. If you are using ODBC, you must get the MyODBC 2.x driver.

- The `scripts/add_long_password` script must be run to convert the `Password` field in the `mysql.user` table to `CHAR(16)`.

- All passwords must be reassigned in the `mysql.user` table to get 62-bit rather than 31-bit passwords.

- The table format hasn't changed, so you don't have to convert any tables.

MySQL 3.20.28 and above can handle the new `user` table format without affecting clients. If you have a MySQL version earlier than 3.20.28, passwords no longer work with it if you convert the `user` table. So to be safe, you should first upgrade to at least Version 3.20.28 and then upgrade to Version 3.21.

The new client code works with a 3.20.x `mysqld` server, so if you experience problems with 3.21.x, you can use the old 3.20.x server without having to recompile the clients again.

If you are not using the `--old-protocol` option to `mysqld`, old clients are unable to connect and should issue the following error message:

```
ERROR: Protocol mismatch. Server Version = 10 Client Version = 9
```

The Perl DBI interface also supports the old `mysqlperl` interface. The only change you have to make if you use `mysqlperl` is to change the arguments to the `connect()` function. The new arguments are: `host`, `database`, `user`, and `password` (note that the `user` and `password` arguments have changed places).

The following changes may affect queries in old applications:

- `HAVING` must be specified before any `ORDER BY` clause.

- The parameters to `LOCATE()` have been swapped.

- There are some new reserved words. The most noticeable are `DATE`, `TIME`, and `TIMESTAMP`.

2.10.8. Upgrading the Grant Tables

Some releases introduce changes to the structure of the grant tables (the tables in the `mysql` database) to add new privileges or features. To make sure that your grant tables are current when you update to a new version of MySQL, you should update your grant tables as well. First make a backup of your `mysql` database, and then use the following procedure.

On Unix or Unix-like systems, update the grant tables by running the `mysql_fix_privilege_tables` script:

```
shell> mysql_fix_privilege_tables
```

You must run this script while the server is running. It attempts to connect to the server running on the local host as `root`. If your `root` account requires a password, indicate the password on the command line. For MySQL 4.1 and up, specify the password like this:

```
shell> mysql_fix_privilege_tables --password=root_password
```

Prior to MySQL 4.1, specify the password like this:

```
shell> mysql_fix_privilege_tables root_password
```

The `mysql_fix_privilege_tables` script performs any actions necessary to convert your grant tables to the current format. You might see some `Duplicate column name` warnings as it runs; you can ignore them.

After running the script, stop the server and restart it.

On Windows systems, there isn't an easy way to update the grant tables until MySQL 4.0.15. From version 4.0.15 on, MySQL distributions include a `mysql_fix_privilege_tables.sql` SQL script that you can run using the `mysql` client. If your MySQL installation is located at `C:\mysql`, the commands look like this:

```
C:\> C:\mysql\bin\mysql -u root -p mysql
mysql> SOURCE C:/mysql/scripts/mysql_fix_privilege_tables.sql
```

If your installation is located in some other directory, adjust the pathnames appropriately.

The `mysql` command will prompt you for the `root` password; enter it when prompted.

As with the Unix procedure, you might see some `Duplicate column name` warnings as `mysql` processes the statements in the `mysql_fix_privilege_tables.sql` script; you can ignore them.

After running the script, stop the server and restart it.

If you are upgrading to MySQL 5.0.1 or later, the grant table upgrade procedure just described adds view-related columns for the `CREATE VIEW` and `SHOW VIEW` privileges. These privileges exist at the global and database levels. Their initial values are assigned as follows:

- In MySQL 5.0.2 or later, `mysql_fix_privilege_tables` copies the `Create_priv` value in the `user` table to the `Create_view_priv` and `Show_view_priv` columns.

- In 5.0.1, the view-related privileges are not enabled for any accounts, so you cannot immediately use `GRANT` to give them to accounts that should have them. To deal with this, first connect to the server as `root` and issue the following statements to give the privileges to the `root` accounts manually with `UPDATE`:

  ```
  mysql> UPDATE mysql.user SET Show_view_priv = 'Y', Create_view_priv = 'Y'
      -> WHERE User = 'root';
  mysql> FLUSH PRIVILEGES;
  ```

  After this, `root` can use `GRANT` to give the view privileges to other accounts. Note: You should issue the statements just shown, `GRANT ALL` does not work at the global and database levels, because `GRANT` requires that you actually possess the privileges you are granting.

2.10.9. Copying MySQL Databases to Another Machine

If you are using MySQL 3.23 or later, you can copy the `.frm`, `.MYI`, and `.MYD` files for `MyISAM` tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See Section 14.1, "The `MyISAM` Storage Engine".

The MySQL `ISAM` data and index files (`.ISD` and `*.ISM`, respectively) are architecture dependent and in some cases operating system dependent. If you want to move your applications to another machine that has a different architecture or operating system than your current machine, you should not try to move a database by simply copying the files to the other machine. Use `mysqldump` instead.

By default, `mysqldump` creates a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

Try `mysqldump --help` to see what options are available. If you are moving the data to a newer version of MySQL, you should use `mysqldump --opt` to take advantage of any optimizations that result in a dump file that is smaller and can be processed faster.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
shell> mysqladmin -h 'other_hostname' create db_name
shell> mysqldump --opt db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use:

```
shell> mysqladmin create db_name
shell> mysqldump -h 'other_hostname' --opt --compress db_name | mysql db_name
```

You can also store the result in a file, then transfer the file to the target machine and load the file into the database there. For example, you can dump a database to a file on the source machine like this:

```
shell> mysqldump --quick db_name | gzip > db_name.contents.gz
```

(The file created in this example is compressed.) Transfer the file containing the database contents to the target machine and run these commands there:

```
shell> mysqladmin create db_name
shell> gunzip < db_name.contents.gz | mysql db_name
```

You can also use mysqldump and mysqlimport to transfer the database. For big tables, this is much faster than simply using mysqldump. In the following commands, DUMPDIR represents the full pathname of the directory you use to store the output from mysqldump.

First, create the directory for the output files and dump the database:

```
shell> mkdir DUMPDIR
shell> mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the DUMPDIR directory to some corresponding directory on the target machine and load the files into MySQL there:

```
shell> mysqladmin create db_name            # create database
shell> cat DUMPDIR/*.sql | mysql db_name    # create tables in database
shell> mysqlimport db_name DUMPDIR/*.txt    # load data into tables
```

Also, don't forget to copy the mysql database because that is where the user, db, and host grant tables are stored. You might have to run commands as the MySQL root user on the new machine until you have the mysql database in place.

After you import the mysql database on the new machine, execute mysqladmin flush-privileges so that the server reloads the grant table information.

2.11. Downgrading MySQL

This section describes what you should do if you are downgrading to an older MySQL version in the unlikely case that the previous version worked better than the new one.

If you are downgrading within the same release series (for example, from 4.0.20 to 4.0.19) the general rule is that you just have to install the new binaries on top of the old ones. There is no need to do anything with the databases. As always, however, it's always a good idea to make a backup.

The following items form a checklist of things you should do whenever you perform an downgrade:

- Read the upgrading section for the release series from which you are downgrading to be sure that it doesn't have any features you really need. Section 2.10, "Upgrading MySQL".

- If there is a downgrading section for that version, please read it, too!

You can always move the MySQL format files and data files between different versions on the same architecture as long as you stay within versions for the same release series of MySQL. The current production release series is 4.1.

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, you can use mysqldump to dump your tables before downgrading. After downgrading, reload the dump file using mysql or mysqlimport to re-create your tables. See Section 2.10.9, "Copying MySQL Databases to Another Machine" for examples.

The normal symptom of a downward-incompatible table format change when you downgrade is that you can't open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are trying to downgrade to.

2. Restart the newer MySQL server you are trying to downgrade from.

3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.

4. Stop the newer MySQL server and restart the older one.

5. Reload the dump file into the older server. Your tables should be accessible.

2.11.1. Downgrading to 4.1

After downgrading from MySQL 5.0, you may see the following information in the `mysql.err` file:

```
Incorrect information in file: './mysql/user.frm'
```

In this case, you can do the following:

1. Start MySQL 5.0.4 (or newer).

2. Run `mysql_fix_privilege_tables`, which will change the `mysql.user` table to a format that both MySQL 4.1 and 5.0 can use.

3. Stop the MySQL server.

4. Start MySQL 4.1.

If the preceding procedure fails, then you should be able to do the following instead:

1. Start MySQL 5.0.4 (or newer).

2. Run `mysqldump --opt --add-drop-table mysql > /tmp/mysql.dump`.

3. Stop the MySQL server.

4. Start MySQL 4.1 with the `--skip-grant` option.

5. Run `mysql mysql < /tmp/mysql.dump`.

6. Run `mysqladmin flush-privileges`.

2.11.2. Downgrading to 4.0

The table format in 4.1 changed to include more and new character set information. Because of this, you must use `mysqldump` to dump any tables you have created with the newer MySQL server. For example, if all the tables in a particular database need to be dumped to be reverted back to MySQL 4.0 format, use this command:

```
shell> mysqldump --create-options --compatible=mysql40 db_name > dump_file
```

Then stop the newer server, restart the older server, and read in the dump file:

```
shell> mysql db_name < dump_file
```

In the special case that you're downgrading `MyISAM` tables, no special treatment is necessary if all columns in the tables contain only numeric columns or string columns (`CHAR`, `VARCHAR`, `TEXT`,

and so forth) that contain only `latin1` data. Your 4.1 tables should be directly usable with a 4.0 server.

If you used the `mysql_fix_privilege_tables` script to upgrade the grant tables, you can either use the preceding method to convert them to back to MySQL 4.0 or do the following in MySQL 4.1 (or above):

```
ALTER TABLE mysql.user CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_c
ALTER TABLE mysql.db CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_ci;
ALTER TABLE mysql.host CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_c
ALTER TABLE mysql.tables_priv CONVERT TO CHARACTER SET latin1 COLLATE latin1_sw
ALTER TABLE mysql.columns_priv CONVERT TO CHARACTER SET latin1 COLLATE latin1_s
ALTER TABLE mysql.func CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_c
```

2.12. Operating System-Specific Notes

2.12.1. Linux Notes

This section discusses issues that have been found to occur on Linux. The first few subsections describe general operating system-related issues, problems that can occur when using binary or source distributions, and post-installation issues. The remaining subsections discuss problems that occur with Linux on specific platforms.

Note that most of these problems occur on older versions of Linux. If you are running a recent version, you may see none of them.

2.12.1.1. Linux Operating System Notes

MySQL needs at least Linux Version 2.0.

Warning: We have seen some strange problems with Linux 2.2.14 and MySQL on SMP systems. We also have reports from some MySQL users that they have encountered serious stability problems using MySQL with kernel 2.2.14. If you are using this kernel, you should upgrade to 2.2.19 (or newer) or to a 2.4 kernel. If you have a multiple-CPU box, then you should seriously consider using 2.4 because it gives you a significant speed boost. Your system should be more stable.

When using LinuxThreads, you should see a minimum of three `mysqld` processes running. These are in fact threads. There is one thread for the LinuxThreads manager, one thread to handle connections, and one thread to handle alarms and signals.

2.12.1.2. Linux Binary Distribution Notes

The Linux-Intel binary and RPM releases of MySQL are configured for the highest possible speed. We are always trying to use the fastest stable compiler available.

The binary release is linked with `-static`, which means you do not normally need to worry about which version of the system libraries you have. You need not install LinuxThreads, either. A program linked with `-static` is slightly larger than a dynamically linked program, but also slightly faster (3-5%). However, one problem with a statically linked program is that you can't use user-defined functions (UDFs). If you are going to write or use UDFs (this is something for C or C++ programmers only), you must compile MySQL yourself using dynamic linking.

A known issue with binary distributions is that on older Linux systems that use `libc` (such as Red Hat 4.x or Slackware), you get some non-fatal problems with hostname resolution. If your system uses `libc` rather than `glibc2`, you probably will encounter some difficulties with hostname resolution and `getpwnam()`. This happens because `glibc` unfortunately depends on some external libraries to implement hostname resolution and `getpwent()`, even when compiled with `-static`. These problems manifest themselves in two ways:

- You may see the following error message when you run `mysql_install_db`:

```
Sorry, the host 'xxxx' could not be looked up
```

You can deal with this by executing `mysql_install_db --force`, which does not execute the `resolveip` test in `mysql_install_db`. The downside is that you can't use hostnames in the grant tables: Except for `localhost`, you must use IP numbers instead. If you are using an old version of MySQL that doesn't support `--force`, you must manually remove the `resolveip` test in `mysql_install` using an editor.

- You also may see the following error when you try to run `mysqld` with the `--user` option:

```
getpwnam: No such file or directory
```

To work around this, start `mysqld` by using the `su` command rather than by specifying the `--user` option. This causes the system itself to change the user ID of the `mysqld` process so that `mysqld` need not do so.

Another solution, which solves both problems, is to not use a binary distribution. Get a MySQL source distribution (in RPM or `tar.gz` format) and install that instead.

On some Linux 2.2 versions, you may get the error `Resource temporarily unavailable` when clients make a lot of new connections to a `mysqld` server over TCP/IP. The problem is that Linux has a delay between the time that you close a TCP/IP socket and the time that the system actually frees it. There is room for only a finite number of TCP/IP slots, so you encounter the resource-unavailable error if clients attempt too many new TCP/IP connections during a short time. For example, you may see the error when you run the MySQL `test-connect` benchmark over TCP/IP.

We have inquired about this problem a few times on different Linux mailing lists but have never been able to find a suitable resolution. The only known "fix" is for the clients to use persistent connections, or, if you are running the database server and clients on the same machine, to use Unix socket file connections rather than TCP/IP connections.

2.12.1.3. Linux Source Distribution Notes

The following notes regarding `glibc` apply only to the situation when you build MySQL yourself. If you are running Linux on an x86 machine, in most cases it is much better for you to just use our binary. We link our binaries against the best patched version of `glibc` we can come up with and with the best compiler options, in an attempt to make it suitable for a high-load server. For a typical user, even for setups with a lot of concurrent connections or tables exceeding the 2GB limit, our binary is the best choice in most cases. After reading the following text, if you are in doubt about what to do, try our binary first to see whether it meets your needs. If you discover that it is not good enough, then you may want to try your own build. In that case, we would appreciate a note about it so that we can build a better binary next time.

MySQL uses LinuxThreads on Linux. If you are using an old Linux version that doesn't have `glibc2`, you must install LinuxThreads before trying to compile MySQL. You can get LinuxThreads at http://dev.mysql.com/downloads/os-linux.html.

Note that `glibc` versions before and including Version 2.1.1 have a fatal bug in `pthread_mutex_timedwait()` handling, which is used when you issue `INSERT DELAYED` statements. We recommend that you not use `INSERT DELAYED` before upgrading `glibc`.

Note that Linux kernel and the LinuxThread library can by default only have 1,024 threads. If you plan to have more than 1,000 concurrent connections, you need to make some changes to LinuxThreads:

- Increase `PTHREAD_THREADS_MAX` in `sysdeps/unix/sysv/linux/bits/local_lim.h` to 4096 and decrease `STACK_SIZE` in

linuxthreads/internals.h to 256KB. The paths are relative to the root of glibc. (Note that MySQL is not stable with around 600-1000 connections if STACK_SIZE is the default of 2MB.)

•   Recompile LinuxThreads to produce a new libpthread.a library, and relink MySQL against it.

The page http://www.volano.com/linuxnotes.html contains additional information about circumventing thread limits in LinuxThreads.

There is another issue that greatly hurts MySQL performance, especially on SMP systems. The mutex implementation in LinuxThreads in glibc 2.1 is very bad for programs with many threads that hold the mutex only for a short time. This produces a paradoxical result: If you link MySQL against an unmodified LinuxThreads, removing processors from an SMP actually improves MySQL performance in many cases. We have made a patch available for glibc 2.1.3 to correct this behavior (http://www.mysql.com/Downloads/Linux/linuxthreads-2.1-patch).

With glibc 2.2.2, MySQL 3.23.36 uses the adaptive mutex, which is much better than even the patched one in glibc 2.1.3. Be warned, however, that under some conditions, the current mutex code in glibc 2.2.2 overspins, which hurts MySQL performance. The likelihood that this condition occurs can be reduced by renicing the mysqld process to the highest priority. We have also been able to correct the overspin behavior with a patch, available at http://www.mysql.com/Downloads/Linux/linuxthreads-2.2.2.patch. It combines the correction of overspin, maximum number of threads, and stack spacing all in one. You need to apply it in the linuxthreads directory with patch -p0 </tmp/linuxthreads-2.2.2.patch. We hope it is included in some form in future releases of glibc 2.2. In any case, if you link against glibc 2.2.2, you still need to correct STACK_SIZE and PTHREAD_THREADS_MAX. We hope that the defaults is corrected to some more acceptable values for high-load MySQL setup in the future, so that the commands needed to produce your own build can be reduced to ./configure; make; make install.

We recommend that you use these patches to build a special static version of libpthread.a and use it only for statically linking against MySQL. We know that the patches are safe for MySQL and significantly improve its performance, but we cannot say anything about other applications. If you link other applications that require LinuxThreads against the patched static version of the library, or build a patched shared version and install it on your system, you do so at your own risk.

If you experience any strange problems during the installation of MySQL, or with some common utilities hanging, it is very likely that they are either library or compiler related. If this is the case, using our binary resolves them.

If you link your own MySQL client programs, you may see the following error at runtime:

```
ld.so.1: fatal: libmysqlclient.so.#:
open failed: No such file or directory
```

This problem can be avoided by one of the following methods:

•   Link clients with the -Wl,r/full/path/to/libmysqlclient.so flag rather than with -Lpath).

•   Copy libmysqclient.so to /usr/lib.

•   Add the pathname of the directory where libmysqlclient.so is located to the LD_RUN_PATH environment variable before running your client.

If you are using the Fujitsu compiler (fcc/FCC), you may have some problems compiling MySQL because the Linux header files are very gcc oriented. The following configure line should work with fcc/FCC:

```
CC=fcc CFLAGS="-O -K fast -K lib -K omitfp -Kpreex -D_GNU_SOURCE \
    -DCONST=const -DNO_STRTOLL_PROTO" \
CXX=FCC CXXFLAGS="-O -K fast -K lib \
    -K omitfp -K preex --no_exceptions --no_rtti -D_GNU_SOURCE \
    -DCONST=const -Dalloca=__builtin_alloca -DNO_STRTOLL_PROTO \
    '-D_EXTERN_INLINE=static __inline'" \
./configure \
    --prefix=/usr/local/mysql --enable-assembler \
    --with-mysqld-ldflags=-all-static --disable-shared \
    --with-low-memory
```

2.12.1.4. Linux Post-Installation Notes

`mysql.server` can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See Section 2.9.2.2, "Starting and Stopping MySQL Automatically".

If MySQL can't open enough files or connections, it may be that you haven't configured Linux to handle enough files.

In Linux 2.2 and onward, you can check the number of allocated file handles as follows:

```
shell> cat /proc/sys/fs/file-max
shell> cat /proc/sys/fs/dquot-max
shell> cat /proc/sys/fs/super-max
```

If you have more than 16MB of memory, you should add something like the following to your init scripts (for example, `/etc/init.d/boot.local` on SuSE Linux):

```
echo 65536 > /proc/sys/fs/file-max
echo 8192 > /proc/sys/fs/dquot-max
echo 1024 > /proc/sys/fs/super-max
```

You can also run the `echo` commands from the command line as `root`, but these settings are lost the next time your computer restarts.

Alternatively, you can set these parameters on startup by using the `sysctl` tool, which is used by many Linux distributions (SuSE has added it as well, beginning with SuSE Linux 8.0). Just put the following values into a file named `/etc/sysctl.conf`:

```
# Increase some values for MySQL
fs.file-max = 65536
fs.dquot-max = 8192
fs.super-max = 1024
```

You should also add the following to `/etc/my.cnf`:

```
[mysqld_safe]
open-files-limit=8192
```

This should allow the server a limit of 8,192 for the combined number of connections and open files.

The `STACK_SIZE` constant in LinuxThreads controls the spacing of thread stacks in the address space. It needs to be large enough so that there is plenty of room for each individual thread stack, but small enough to keep the stack of some threads from running into the global `mysqld` data. Unfortunately, as we have experimentally discovered, the Linux implementation of `mmap()` successfully unmaps a mapped region if you ask it to map out an address currently in use, zeroing out the data on the entire page instead of returning an error. So, the safety of `mysqld` or any other threaded application depends on "gentlemanly" behavior of the code that creates threads. The user must take

measures to make sure that the number of running threads at any time is sufficiently low for thread stacks to stay away from the global heap. With `mysqld`, you should enforce this behavior by setting a reasonable value for the `max_connections` variable.

If you build MySQL yourself, you can patch LinuxThreads for better stack use. See Section 2.12.1.3, "Linux Source Distribution Notes". If you do not want to patch LinuxThreads, you should set `max_connections` to a value no higher than 500. It should be even less if you have a large key buffer, large heap tables, or some other things that make `mysqld` allocate a lot of memory, or if you are running a 2.2 kernel with a 2GB patch. If you are using our binary or RPM version 3.23.25 or later, you can safely set `max_connections` at 1500, assuming no large key buffer or heap tables with lots of data. The more you reduce `STACK_SIZE` in LinuxThreads the more threads you can safely create. We recommend values between 128KB and 256KB.

If you use a lot of concurrent connections, you may suffer from a "feature" in the 2.2 kernel that attempts to prevent fork bomb attacks by penalizing a process for forking or cloning a child. This causes MySQL not to scale well as you increase the number of concurrent clients. On single-CPU systems, we have seen this manifested as very slow thread creation: It may take a long time to connect to MySQL (as long as one minute), and it may take just as long to shut it down. On multiple-CPU systems, we have observed a gradual drop in query speed as the number of clients increases. In the process of trying to find a solution, we have received a kernel patch from one of our users who claimed it made a lot of difference for his site. The patch is available at http://www.mysql.com/Downloads/Patches/linux-fork.patch. We have done rather extensive testing of this patch on both development and production systems. It has significantly improved MySQL performance without causing any problems and we recommend it to our users who still run high-load servers on 2.2 kernels.

This issue has been fixed in the 2.4 kernel, so if you are not satisfied with the current performance of your system, rather than patching your 2.2 kernel, it might be easier to upgrade to 2.4. On SMP systems, upgrading also gives you a nice SMP boost in addition to fixing the fairness bug.

We have tested MySQL on the 2.4 kernel on a two-CPU machine and found MySQL scales *much* better. There was virtually no slowdown on query throughput all the way up to 1,000 clients, and the MySQL scaling factor (computed as the ratio of maximum throughput to the throughput for one client) was 180%. We have observed similar results on a four-CPU system: Virtually no slowdown as the number of clients was increased up to 1,000, and a 300% scaling factor. Based on these results, for a high-load SMP server using a 2.2 kernel, we definitely recommend upgrading to the 2.4 kernel at this point.

We have discovered that it is essential to run the `mysqld` process with the highest possible priority on the 2.4 kernel to achieve maximum performance. This can be done by adding a `renice -20 $$` command to `mysqld_safe`. In our testing on a four-CPU machine, increasing the priority resulted in a 60% throughput increase with 400 clients.

We are currently also trying to collect more information on how well MySQL performs with a 2.4 kernel on four-way and eight-way systems. If you have access such a system and have done some benchmarks, please send an email message to <benchmarks@mysql.com> with the results. We will review them for inclusion in the manual.

If you see a dead `mysqld` server process with `ps`, this usually means that you have found a bug in MySQL or you have a corrupted table. See Section A.4.2, "What to Do If MySQL Keeps Crashing".

To get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` option. Note that you also probably need to raise the core file size by adding `ulimit -c 1000000` to `mysqld_safe` or starting `mysqld_safe` with `--core-file-size=1000000`. See Section 5.1.3, "mysqld_safe — MySQL Server Startup Script".

2.12.1.5. Linux x86 Notes

MySQL requires `libc` Version 5.4.12 or newer. It's known to work with `libc` 5.4.46. `glibc` Version 2.0.6 and later should also work. There have been some problems with the `glibc` RPMs from Red Hat, so if you have problems, check whether there are any updates. The `glibc` 2.0.7-19 and 2.0.7-29 RPMs are known to work.

If you are using Red Hat 8.0 or a new `glibc` 2.2.x library, you may see `mysqld` die in `gethostbyaddr()`. This happens because the new `glibc` library requires a stack size greater than 128KB for this call. To fix the problem, start `mysqld` with the `--thread-stack=192K` option. (Use `-O thread_stack=192K` before MySQL 4.) This stack size is the default on MySQL 4.0.10 and above, so you should not see the problem.

If you are using `gcc` 3.0 and above to compile MySQL, you must install the `libstdc++v3` library before compiling MySQL; if you don't do this, you get an error about a missing `__cxa_pure_virtual` symbol during linking.

On some older Linux distributions, `configure` may produce an error like this:

```
Syntax error in sched.h. Change _P to __P in the
/usr/include/sched.h file.
See the Installation chapter in the Reference Manual.
```

Just do what the error message says. Add an extra underscore to the `_P` macro name that has only one underscore, then try again.

You may get some warnings when compiling. Those shown here can be ignored:

```
mysqld.cc -o objs-thread/mysqld.o
mysqld.cc: In function `void init_signals()':
mysqld.cc:315: warning: assignment of negative value `-1' to
`long unsigned int'
mysqld.cc: In function `void * signal_hand(void *)':
mysqld.cc:346: warning: assignment of negative value `-1' to
`long unsigned int'
```

If `mysqld` always dumps core when it starts, the problem may be that you have an old `/lib/libc.a`. Try renaming it, then remove `sql/mysqld` and do a new `make install` and try again. This problem has been reported on some Slackware installations.

If you get the following error when linking `mysqld`, it means that your `libg++.a` is not installed correctly:

```
/usr/lib/libc.a(putc.o): In function `_IO_putc':
putc.o(.text+0x0): multiple definition of `_IO_putc'
```

You can avoid using `libg++.a` by running `configure` like this:

```
shell> CXX=gcc ./configure
```

If `mysqld` crashes immediately and you are running Red Hat Version 5.0 with a version of `glibc` older than 2.0.7-5, you should make sure that you have installed all `glibc` patches. There is a lot of information about this in the MySQL mail archives, available online at http://lists.mysql.com/.

2.12.1.6. Linux SPARC Notes

In some implementations, `readdir_r()` is broken. The symptom is that the `SHOW DATABASES` statement always returns an empty set. This can be fixed by removing `HAVE_READDIR_R` from `config.h` after configuring and before compiling.

2.12.1.7. Linux Alpha Notes

MySQL 3.23.12 is the first MySQL version that is tested on Linux-Alpha. If you plan to use MySQL on Linux-Alpha, you should ensure that you have this version or newer.

We have tested MySQL on Alpha with our benchmarks and test suite, and it appears to work nicely.

We currently build the MySQL binary packages on SuSE Linux 7.0 for AXP, kernel 2.4.4-SMP, Compaq C compiler (V6.2-505) and Compaq C++ compiler (V6.3-006) on a Compaq DS20 machine with an Alpha EV6 processor.

You can find the preceding compilers at http://www.support.compaq.com/alpha-tools/. By using these compilers rather than `gcc`, we get about 9-14% better MySQL performance.

Note that until MySQL version 3.23.52 and 4.0.2, we optimized the binary for the current CPU only (by using the `-fast` compile option). This means that for older versions, you can use our Alpha binaries only if you have an Alpha EV6 processor.

For all following releases, we added the `-arch generic` flag to our compile options, which makes sure that the binary runs on all Alpha processors. We also compile statically to avoid library problems. The `configure` command looks like this:

```
CC=ccc CFLAGS="-fast -arch generic" CXX=cxx \
CXXFLAGS="-fast -arch generic -noexceptions -nortti" \
./configure --prefix=/usr/local/mysql --disable-shared \
    --with-extra-charsets=complex --enable-thread-safe-client \
    --with-mysqld-ldflags=-non_shared --with-client-ldflags=-non_shared
```

If you want to use `egcs`, the following `configure` line worked for us:

```
CFLAGS="-O3 -fomit-frame-pointer" CXX=gcc \
CXXFLAGS="-O3 -fomit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti" \
./configure --prefix=/usr/local/mysql --disable-shared
```

Some known problems when running MySQL on Linux-Alpha:

- Debugging threaded applications like MySQL does not work with `gdb 4.18`. You should use `gdb` 5.1 instead.

- If you try linking `mysqld` statically when using `gcc`, the resulting image dumps core at startup time. In other words, *do not* use `--with-mysqld-ldflags=-all-static` with `gcc`.

2.12.1.8. Linux PowerPC Notes

MySQL should work on MkLinux with the newest `glibc` package (tested with `glibc` 2.0.7).

2.12.1.9. Linux MIPS Notes

To get MySQL to work on Qube2 (Linux Mips), you need the newest `glibc` libraries. `glibc-2.0.7-29C2` is known to work. You must also use the `egcs` C++ compiler (egcs 1.0.2-9, `gcc` 2.95.2 or newer).

2.12.1.10. Linux IA-64 Notes

To get MySQL to compile on Linux IA-64, we use the following `configure` command for building with `gcc` 2.96:

```
CC=gcc \
CFLAGS="-O3 -fno-omit-frame-pointer" \
CXX=gcc \
CXXFLAGS="-O3 -fno-omit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti" \
    ./configure --prefix=/usr/local/mysql \
    "--with-comment=Official MySQL binary" \
    --with-extra-charsets=complex
```

On IA-64, the MySQL client binaries use shared libraries. This means that if you install our binary distribution at a location other than `/usr/local/mysql`, you need to add the path of the directory where you have `libmysqlclient.so` installed either to the `/etc/ld.so.conf` file or to the value of your `LD_LIBRARY_PATH` environment variable.

See Section A.3.1, "Problems Linking to the MySQL Client Library".

2.12.2. Mac OS X Notes

On Mac OS X, `tar` cannot handle long filenames. If you need to unpack a `.tar.gz` distribution, use `gnutar` instead.

2.12.2.1. Mac OS X 10.x (Darwin)

MySQL should work without bigger problems on Mac OS X 10.x (Darwin).

The known problems are:

- The connection times (`wait_timeout`, `interactive_timeout` and `net_read_timeout`) values are not honored. The symptom is that persistent connections can hang for a very long time without getting closed down and that a 'kill' for a thread will not take affect until the thread does it a new command

  This is probably a signal handling problem in the thread library where the signal doesn't break a pending read and we hope that a future update to the thread libraries will fix this.

Our binary for Mac OS X is compiled on Darwin 6.3 with the following `configure` line:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc \
CXXFLAGS="-O3 -fno-omit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti" \
    ./configure --prefix=/usr/local/mysql \
    --with-extra-charsets=complex --enable-thread-safe-client \
    --enable-local-infile --disable-shared
```

See Section 2.5, "Installing MySQL on Mac OS X".

2.12.2.2. Mac OS X Server 1.2 (Rhapsody)

For current versions of Mac OS X Server, no operating system changes are necessary before compiling MySQL. Compiling for the Server platform is the same as for the client version of Mac OS X. (However, note that MySQL comes preinstalled on Mac OS X Server, so you need not build it yourself.)

For older versions (Mac OS X Server 1.2, a.k.a. Rhapsody), you must first install a pthread package before trying to configure MySQL.

See Section 2.5, "Installing MySQL on Mac OS X".

2.12.3. Solaris Notes

On Solaris, you may run into trouble even before you get the MySQL distribution unpacked! Solaris `tar` can't handle long filenames, so you may see an error like this when you unpack MySQL:

```
x mysql-3.22.12-beta/bench/Results/ATIS-mysql_odbc-NT_4.0-cmp-db2,
informix,ms-sql,mysql,oracle,solid,sybase, 0 bytes, 0 tape blocks
tar: directory checksum error
```

In this case, you must use GNU `tar` (`gtar`) to unpack the distribution. You can find a precompiled copy for Solaris at http://dev.mysql.com/downloads/os-solaris.html.

Sun native threads work only on Solaris 2.5 and higher. For Version 2.4 and earlier, MySQL automatically uses MIT-pthreads. See Section 2.8.5, "MIT-pthreads Notes".

If you get the following error from `configure`, it means that you have something wrong with your compiler installation:

```
checking for restartable system calls... configure: error can not
run test programs while cross compiling
```

In this case, you should upgrade your compiler to a newer version. You may also be able to solve this problem by inserting the following row into the `config.cache` file:

```
ac_cv_sys_restartable_syscalls=${ac_cv_sys_restartable_syscalls='no'}
```

If you are using Solaris on a SPARC, the recommended compiler is `gcc` 2.95.2 or 3.2. You can find this at http://gcc.gnu.org/. Note that `egcs` 1.1.1 and `gcc` 2.8.1 don't work reliably on SPARC!

The recommended `configure` line when using `gcc` 2.95.2 is:

```
CC=gcc CFLAGS="-O3" \
CXX=gcc CXXFLAGS="-O3 -felide-constructors -fno-exceptions -fno-rtti" \
./configure --prefix=/usr/local/mysql --with-low-memory \
    --enable-assembler
```

If you have an UltraSPARC system, you can get 4% better performance by adding `-mcpu=v8 -Wa,-xarch=v8plusa` to the `CFLAGS` and `CXXFLAGS` environment variables.

If you have Sun's Forte 5.0 (or newer) compiler, you can run `configure` like this:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt" \
CXX=CC CXXFLAGS="-noex -mt" \
./configure --prefix=/usr/local/mysql --enable-assembler
```

To create a 64-bit binary with Sun's Forte compiler, use the following configuration options:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt -xarch=v9" \
CXX=CC CXXFLAGS="-noex -mt -xarch=v9" ASFLAGS="-xarch=v9" \
./configure --prefix=/usr/local/mysql --enable-assembler
```

To create a 64-bit Solaris binary using `gcc`, add `-m64` to `CFLAGS` and `CXXFLAGS` and remove `--enable-assembler` from the `configure` line. This works only with MySQL 4.0 and up; MySQL 3.23 does not include the required modifications to support this.

In the MySQL benchmarks, we got a 4% speedup on an UltraSPARC when using Forte 5.0 in 32-bit mode compared to using `gcc` 3.2 with the `-mcpu` flag.

If you create a 64-bit `mysqld` binary, it is 4% slower than the 32-bit binary, but can handle more threads and memory.

When using Solaris 10 for x86_64, you should mount any filesystems on which you intend to store InnoDB files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the InnoDB storage engine on this platform.

If you get a problem with `fdatasync` or `sched_yield`, you can fix this by adding `LIBS=-lrt` to the `configure` line

For compilers older than WorkShop 5.3, you might have to edit the `configure` script. Change this line:

```
#if !defined(__STDC__) || __STDC__ != 1
```

To this:

```
#if !defined(__STDC__)
```

If you turn on `__STDC__` with the `-Xc` option, the Sun compiler can't compile with the Solaris `pthread.h` header file. This is a Sun bug (broken compiler or broken include file).

If `mysqld` issues the following error message when you run it, you have tried to compile MySQL with the Sun compiler without enabling the `-mt` multi-thread option:

```
libc internal error: _rmutex_unlock: rmutex not held
```

Add `-mt` to `CFLAGS` and `CXXFLAGS` and recompile.

If you are using the SFW version of `gcc` (which comes with Solaris 8), you must add `/opt/sfw/lib` to the environment variable `LD_LIBRARY_PATH` before running `configure`.

If you are using the `gcc` available from `sunfreeware.com`, you may have many problems. To avoid this, you should recompile `gcc` and GNU `binutils` on the machine where you are running them.

If you get the following error when compiling MySQL with `gcc`, it means that your `gcc` is not configured for your version of Solaris:

```
shell> gcc -O3 -g -O2 -DDBUG_OFF  -o thr_alarm ...
./thr_alarm.c: In function `signal_hand':
./thr_alarm.c:556: too many arguments to function `sigwait'
```

The proper thing to do in this case is to get the newest version of `gcc` and compile it with your current `gcc` compiler. At least for Solaris 2.5, almost all binary versions of `gcc` have old, unusable include files that break all programs that use threads, and possibly other programs!

Solaris doesn't provide static versions of all system libraries (`libpthreads` and `libdl`), so you can't compile MySQL with `--static`. If you try to do so, you get one of the following errors:

```
ld: fatal: library -ldl: not found
undefined reference to `dlopen'
cannot find -lrt
```

If you link your own MySQL client programs, you may see the following error at runtime:

```
ld.so.1: fatal: libmysqlclient.so.#:
open failed: No such file or directory
```

This problem can be avoided by one of the following methods:

- Link clients with the `-Wl,r/full/path/to/libmysqlclient.so` flag rather than with `-Lpath`).

- Copy `libmysqclient.so` to `/usr/lib`.

- Add the pathname of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable before running your client.

If you have problems with `configure` trying to link with `-lz` when you don't have `zlib` installed, you have two options:

- If you want to be able to use the compressed communication protocol, you need to get and install `zlib` from `ftp.gnu.org`.

- Run `configure` with the `--with-named-z-libs=no` option when building MySQL.

If you are using `gcc` and have problems with loading user-defined functions (UDFs) into MySQL, try adding `-lgcc` to the link line for the UDF.

If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.

If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` option as a workaround for this. (Use `-O back_log=50` before MySQL 4.)

Solaris doesn't support core files for `setuid()` applications, so you can't get a core file from `mysqld` if you are using the `--user` option.

2.12.3.1. Solaris 2.7/2.8 Notes

Normally, you can use a Solaris 2.6 binary on Solaris 2.7 and 2.8. Most of the Solaris 2.6 issues also apply for Solaris 2.7 and 2.8.

MySQL 3.23.4 and above should be able to detect new versions of Solaris automatically and enable workarounds for the following problems.

Solaris 2.7 / 2.8 has some bugs in the include files. You may see the following error when you use `gcc`:

```
/usr/include/widec.h:42: warning: `getwc' redefined
/usr/include/wchar.h:326: warning: this is the location of the previous
definition
```

If this occurs, you can fix the problem by copying `/usr/include/widec.h` to `.../lib/gcc-lib/os/gcc-version/include` and changing line 41 from this:

```
#if     !defined(lint) && !defined(__lint)
```

To this:

```
#if     !defined(lint) && !defined(__lint) && !defined(getwc)
```

Alternatively, you can edit `/usr/include/widec.h` directly. Either way, after you make the fix, you should remove `config.cache` and run `configure` again.

If you get the following errors when you run `make`, it's because `configure` didn't detect the `curses.h` file (probably because of the error in `/usr/include/widec.h`):

```
In file included from mysql.cc:50:
/usr/include/term.h:1060: syntax error before `,'
/usr/include/term.h:1081: syntax error before `;'
```

The solution to this problem is to do one of the following:

- Configure with `CFLAGS=-DHAVE_CURSES_H` `CXXFLAGS=-DHAVE_CURSES_H` `./configure`.

- Edit `/usr/include/widec.h` as indicated in the preceding discussion and re-run `configure`.

- Remove the `#define HAVE_TERM` line from the `config.h` file and run `make` again.

If your linker can't find `-lz` when linking client programs, the problem is probably that your `libz.so` file is installed in `/usr/local/lib`. You can fix this problem by one of the following methods:

- Add `/usr/local/lib` to `LD_LIBRARY_PATH`.

- Add a link to `libz.so` from `/lib`.

- If you are using Solaris 8, you can install the optional `zlib` from your Solaris 8 CD distribution.

- Run `configure` with the `--with-named-z-libs=no` option when building MySQL.

2.12.3.2. Solaris x86 Notes

On Solaris 8 on x86, `mysqld` dumps core if you remove the debug symbols using `strip`.

If you are using `gcc` or `egcs` on Solaris x86 and you experience problems with core dumps under load, you should use the following `configure` command:

```
CC=gcc CFLAGS="-O3 -fomit-frame-pointer -DHAVE_CURSES_H" \
CXX=gcc \
CXXFLAGS="-O3 -fomit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti -DHAVE_CURSES_H" \
./configure --prefix=/usr/local/mysql
```

This avoids problems with the `libstdc++` library and with C++ exceptions.

If this doesn't help, you should compile a debug version and run it with a trace file or under `gdb`. See Section F.1.3, "Debugging `mysqld` under `gdb`".

2.12.4. BSD Notes

This section provides information about using MySQL on variants of BSD Unix.

2.12.4.1. FreeBSD Notes

FreeBSD 4.x or newer is recommended for running MySQL, because the thread package is much more integrated. To get a secure and stable system, you should use only FreeBSD kernels that are marked `-RELEASE`.

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at http://www.freebsd.org/. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.

- Automatic configuration and build.

- Startup scripts installed in `/usr/local/etc/rc.d`.

- The ability to use `pkg_info -L` to see which files are installed.

- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

It is recommended you use MIT-pthreads on FreeBSD 2.x, and native threads on Versions 3 and up. It is possible to run with native threads on some late 2.2.x versions, but you may encounter problems shutting down `mysqld`.

Unfortunately, certain function calls on FreeBSD are not yet fully thread-safe. Most notably, this includes the `gethostbyname()` function, which is used by MySQL to convert hostnames into IP addresses. Under certain circumstances, the `mysqld` process suddenly causes 100% CPU load and is unresponsive. If you encounter this problem, try to start MySQL using the `--skip-name-resolve` option.

Alternatively, you can link MySQL on FreeBSD 4.x against the LinuxThreads library, which avoids a few of the problems that the native FreeBSD thread implementation has. For a very good comparison of LinuxThreads versus native threads, see Jeremy Zawodny's article *FreeBSD or Linux for your MySQL Server?* at http://jeremy.zawodny.com/blog/archives/000697.html.

Known problem when using LinuxThreads on FreeBSD is:

- The connection times (`wait_timeout`, `interactive_timeout` and `net_read_timeout`) values are not honored. The symptom is that persistent connections can hang for a very long time without getting closed down and that a 'kill' for a thread will not take affect until the thread does it a new command

  This is probably a signal handling problem in the thread library where the signal doesn't break a pending read. This is supposed to be fixed in FreeBSD 5.0

The MySQL build process requires GNU make (`gmake`) to work. If GNU `make` is not available, you must install it first before compiling MySQL.

The recommended way to compile and install MySQL on FreeBSD with `gcc` (2.95.2 and up) is:

```
CC=gcc CFLAGS="-O2 -fno-strength-reduce" \
    CXX=gcc CXXFLAGS="-O2 -fno-rtti -fno-exceptions \
    -felide-constructors -fno-strength-reduce" \
    ./configure --prefix=/usr/local/mysql --enable-assembler
gmake
gmake install
cd /usr/local/mysql
bin/mysql_install_db --user=mysql
bin/mysqld_safe &
```

If you notice that `configure` uses MIT-pthreads, you should read the MIT-pthreads notes. See Section 2.8.5, "MIT-pthreads Notes".

If you get an error from `make install` that it can't find `/usr/include/pthreads`, `configure` didn't detect that you need MIT-pthreads. To fix this problem, remove `config.cache`, then re-run `configure` with the `--with-mit-threads` option.

Be sure that your name resolver setup is correct. Otherwise, you may experience resolver delays or failures when connecting to `mysqld`. Also make sure that the `localhost` entry in the `/etc/hosts` file is correct. The file should start with a line similar to this:

```
127.0.0.1        localhost localhost.your.domain
```

FreeBSD is known to have a very low default file handle limit. See Section A.2.17, "File Not Found". Start the server by using the `--open-files-limit` option for `mysqld_safe`, or raise the limits for the `mysqld` user in `/etc/login.conf` and rebuild it with `cap_mkdb /etc/login.conf`. Also be sure that you set the appropriate class for this user in the password file if you are not using the default (use `chpass mysqld-user-name`). See Section 5.1.3, "mysqld_safe — MySQL Server Startup Script".

If you have a lot of memory, you should consider rebuilding the kernel to allow MySQL to use more than 512MB of RAM. Take a look at `option MAXDSIZ` in the LINT config file for more information.

If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Appendix G, *Environment Variables*.

2.12.4.2. NetBSD Notes

To compile on NetBSD, you need GNU `make`. Otherwise, the build process fails when `make` tries to run `lint` on C++ files.

2.12.4.3. OpenBSD 2.5 Notes

On OpenBSD Version 2.5, you can compile MySQL with native threads with the following options:

```
CFLAGS=-pthread CXXFLAGS=-pthread ./configure --with-mit-threads=no
```

2.12.4.4. OpenBSD 2.8 Notes

Our users have reported that OpenBSD 2.8 has a threading bug that causes problems with MySQL. The OpenBSD Developers have fixed the problem, but as of January 25, 2001, it's only available in the "-current" branch. The symptoms of this threading bug are slow response, high load, high CPU usage, and crashes.

If you get an error like `Error in accept:: Bad file descriptor` or error 9 when trying to open tables or directories, the problem is probably that you have not allocated enough file descriptors for MySQL.

In this case, try starting `mysqld_safe` as `root` with the following options:

```
mysqld_safe --user=mysql --open-files-limit=2048 &
```

2.12.4.5. BSD/OS Version 2.x Notes

If you get the following error when compiling MySQL, your `ulimit` value for virtual memory is too low:

```
item_func.h: In method
`Item_func_ge::Item_func_ge(const Item_func_ge &)':
item_func.h:28: virtual memory exhausted
make[2]: *** [item_func.o] Error 1
```

Try using `ulimit -v 80000` and run `make` again. If this doesn't work and you are using `bash`, try switching to `csh` or `sh`; some BSDI users have reported problems with `bash` and `ulimit`.

If you are using `gcc`, you may also use have to use the `--with-low-memory` flag for `configure` to be able to compile `sql_yacc.cc`.

If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Ap-

pendix G, *Environment Variables*.

2.12.4.6. BSD/OS Version 3.x Notes

Upgrade to BSD/OS Version 3.1. If that is not possible, install BSDIpatch M300-038.

Use the following command when configuring MySQL:

```
env CXX=shlicc++ CC=shlicc2 \
./configure \
    --prefix=/usr/local/mysql \
    --localstatedir=/var/mysql \
    --without-perl \
    --with-unix-socket-path=/var/mysql/mysql.sock
```

The following is also known to work:

```
env CC=gcc CXX=gcc CXXFLAGS=-O3 \
./configure \
    --prefix=/usr/local/mysql \
    --with-unix-socket-path=/var/mysql/mysql.sock
```

You can change the directory locations if you wish, or just use the defaults by not specifying any locations.

If you have problems with performance under heavy load, try using the `--skip-thread-priority` option to `mysqld`. This runs all threads with the same priority. On BSDI Version 3.1, this gives better performance, at least until BSDI fixes its thread scheduler.

If you get the error `virtual memory exhausted` while compiling, you should try using `ulimit -v 80000` and running `make` again. If this doesn't work and you are using `bash`, try switching to `csh` or `sh`; some BSDI users have reported problems with `bash` and `ulimit`.

2.12.4.7. BSD/OS Version 4.x Notes

BSDI Version 4.x has some thread-related bugs. If you want to use MySQL on this, you should install all thread-related patches. At least M400-023 should be installed.

On some BSDI Version 4.x systems, you may get problems with shared libraries. The symptom is that you can't execute any client programs, for example, `mysqladmin`. In this case, you need to reconfigure not to use shared libraries with the `--disable-shared` option to configure.

Some customers have had problems on BSDI 4.0.1 that the `mysqld` binary after a while can't open tables. This is because some library/system-related bug causes `mysqld` to change current directory without having asked for that to happen.

The fix is to either upgrade MySQL to at least version 3.23.34 or, after running `configure`, remove the line `#define HAVE_REALPATH` from `config.h` before running `make`.

Note that this means that you can't symbolically link a database directories to another database directory or symbolic link a table to another database on BSDI. (Making a symbolic link to another disk is okay).

2.12.5. Other Unix Notes

2.12.5.1. HP-UX Version 10.20 Notes

There are a couple of small problems when compiling MySQL on HP-UX. We recommend that you use `gcc` instead of the HP-UX native compiler, because `gcc` produces better code.

We recommend using `gcc` 2.95 on HP-UX. Don't use high optimization flags (such as `-O6`) because they may not be safe on HP-UX.

The following `configure` line should work with `gcc` 2.95:

```
CFLAGS="-I/opt/dce/include -fpic" \
CXXFLAGS="-I/opt/dce/include -felide-constructors -fno-exceptions \
-fno-rtti" \
CXX=gcc \
./configure --with-pthread \
    --with-named-thread-libs='-ldce' \
    --prefix=/usr/local/mysql --disable-shared
```

The following `configure` line should work with `gcc` 3.1:

```
CFLAGS="-DHPUX -I/opt/dce/include -O3 -fPIC" CXX=gcc \
CXXFLAGS="-DHPUX -I/opt/dce/include -felide-constructors \
    -fno-exceptions -fno-rtti -O3 -fPIC" \
./configure --prefix=/usr/local/mysql \
    --with-extra-charsets=complex --enable-thread-safe-client \
    --enable-local-infile  --with-pthread \
    --with-named-thread-libs=-ldce --with-lib-ccflags=-fPIC
    --disable-shared
```

2.12.5.2. HP-UX Version 11.x Notes

For HP-UX Version 11.x, we recommend MySQL 3.23.15 or later.

Because of some critical bugs in the standard HP-UX libraries, you should install the following patches before trying to run MySQL on HP-UX 11.0:

```
PHKL_22840 Streams cumulative
PHNE_22397 ARPA cumulative
```

This solves the problem of getting `EWOULDBLOCK` from `recv()` and `EBADF` from `accept()` in threaded applications.

If you are using `gcc` 2.95.1 on an unpatched HP-UX 11.x system, you may get the following error:

```
In file included from /usr/include/unistd.h:11,
                 from ../include/global.h:125,
                 from mysql_priv.h:15,
                 from item.cc:19:
/usr/include/sys/unistd.h:184: declaration of C function ...
/usr/include/sys/pthread.h:440: previous declaration ...
In file included from item.h:306,
                 from mysql_priv.h:158,
                 from item.cc:19:
```

The problem is that HP-UX doesn't define `pthreads_atfork()` consistently. It has conflicting prototypes in `/usr/include/sys/unistd.h:184` and `/usr/include/sys/pthread.h:440`.

One solution is to copy `/usr/include/sys/unistd.h` into `mysql/include` and edit `unistd.h` and change it to match the definition in `pthread.h`. Look for this line:

```
extern int pthread_atfork(void (*prepare)(), void (*parent)(),
                                  void (*child)());
```

Change it to look like this:

```
extern int pthread_atfork(void (*prepare)(void), void (*parent)(void),
                                  void (*child)(void));
```

After making the change, the following `configure` line should work:

```
CFLAGS="-fomit-frame-pointer -O3 -fpic" CXX=gcc \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti -O3" \
./configure --prefix=/usr/local/mysql --disable-shared
```

If you are using MySQL 4.0.5 with the HP-UX compiler, you can use the following command (which has been tested with `cc` B.11.11.04):

```
CC=cc CXX=aCC CFLAGS=+DD64 CXXFLAGS=+DD64 ./configure \
    --with-extra-character-set=complex
```

You can ignore any errors of the following type:

```
aCC: warning 901: unknown option: `-3': use +help for online
documentation
```

If you get the following error from `configure`, verify that you don't have the path to the K&R compiler before the path to the HP-UX C and C++ compiler:

```
checking for cc option to accept ANSI C... no
configure: error: MySQL requires an ANSI C compiler (and a C++ compiler).
Try gcc. See the Installation chapter in the Reference Manual.
```

Another reason for not being able to compile is that you didn't define the +DD64 flags as just described.

Another possibility for HP-UX 11 is to use MySQL binaries for HP-UX 10.20. We have received reports from some users that these binaries work fine on HP-UX 11.00. If you encounter problems, be sure to check your HP-UX patch level.

2.12.5.3. IBM-AIX notes

Automatic detection of `xlC` is missing from Autoconf, so a number of variables need to be set before running `configure`. The following example uses the IBM compiler:

```
export CC="xlc_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192 "
export CXX="xlC_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192"
export CFLAGS="-I /usr/local/include"
export LDFLAGS="-L /usr/local/lib"
export CPPFLAGS=$CFLAGS
export CXXFLAGS=$CFLAGS

./configure --prefix=/usr/local \
            --localstatedir=/var/mysql \
            --sbindir='/usr/local/bin' \
            --libexecdir='/usr/local/bin' \
            --enable-thread-safe-client \
            --enable-large-files
```

The preceding options are used to compile the MySQL distribution that can be found at http://www-frec.bull.com/.

If you change the `-O3` to `-O2` in the preceding `configure` line, you must also remove the `-qstrict` option. This is a limitation in the IBM C compiler.

If you are using `gcc` or `egcs` to compile MySQL, you *must* use the `-fno-exceptions` flag, because the exception handling in `gcc/egcs` is not thread-safe! (This is tested with `egcs` 1.1.) There are also some known problems with IBM's assembler that may cause it to generate bad code when used with `gcc`.

We recommend the following `configure` line with `egcs` and `gcc` 2.95 on AIX:

```
CC="gcc -pipe -mcpu=power -Wa,-many" \
CXX="gcc -pipe -mcpu=power -Wa,-many" \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti" \
./configure --prefix=/usr/local/mysql --with-low-memory
```

The `-Wa,-many` option is necessary for the compile to be successful. IBM is aware of this problem but is in no hurry to fix it because of the workaround that is available. We don't know if the `-fno-exceptions` is required with `gcc` 2.95, but because MySQL doesn't use exceptions and the option generates faster code, we recommend that you should always use it with `egcs` / `gcc`.

If you get a problem with assembler code, try changing the `-mcpu=`xxx option to match your CPU. Typically `power2`, `power`, or `powerpc` may need to be used. Alternatively, you might need to use `604` or `604e`. We are not positive but suspect that `power` would likely be safe most of the time, even on a power2 machine.

If you don't know what your CPU is, execute a `uname -m` command. It produces a string that looks like `000514676700`, with a format of xxyyyyyymmss where xx and ss are always `00`, yyyyyy is a unique system ID and mm is the ID of the CPU Planar. A chart of these values can be found at http://www16.boulder.ibm.com/pseries/en_US/cmds/aixcmds5/uname.htm.

This gives you a machine type and a machine model you can use to determine what type of CPU you have.

If you have problems with signals (MySQL dies unexpectedly under high load), you may have found an OS bug with threads and signals. In this case, you can tell MySQL not to use signals by configuring as follows:

```
CFLAGS=-DDONT_USE_THR_ALARM CXX=gcc \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti \
-DDONT_USE_THR_ALARM" \
./configure --prefix=/usr/local/mysql --with-debug \
    --with-low-memory
```

This doesn't affect the performance of MySQL, but has the side effect that you can't kill clients that are "sleeping" on a connection with `mysqladmin kill` or `mysqladmin shutdown`. Instead, the client dies when it issues its next command.

On some versions of AIX, linking with `libbind.a` makes `getservbyname()` dump core. This is an AIX bug and should be reported to IBM.

For AIX 4.2.1 and `gcc`, you have to make the following changes.

After configuring, edit `config.h` and `include/my_config.h` and change the line that says this:

```
#define HAVE_SNPRINTF 1
```

to this:

```
#undef HAVE_SNPRINTF
```

And finally, in `mysqld.cc`, you need to add a prototype for `initgroups()`.

```
#ifdef _AIX41
extern "C" int initgroups(const char *,int);
#endif
```

If you need to allocate a lot of memory to the `mysqld` process, it's not enough to just use `ulimit`

-d unlimited. You may also have to modify `mysqld_safe` to add a line something like this:

```
export LDR_CNTRL='MAXDATA=0x80000000'
```

You can find more information about using a lot of memory at ht-tp://publib16.boulder.ibm.com/pseries/en_US/aixprggd/genprogc/lrg_prg_support.htm.

2.12.5.4. SunOS 4 Notes

On SunOS 4, MIT-pthreads is needed to compile MySQL. This in turn means you need GNU `make`.

Some SunOS 4 systems have problems with dynamic libraries and `libtool`. You can use the following `configure` line to avoid this problem:

```
./configure --disable-shared --with-mysqld-ldflags=-all-static
```

When compiling `readline`, you may get warnings about duplicate defines. These can be ignored.

When compiling `mysqld`, there are some `implicit declaration of function` warnings. These can be ignored.

2.12.5.5. Alpha-DEC-UNIX Notes (Tru64)

If you are using `egcs` 1.1.2 on Digital Unix, you should upgrade to `gcc` 2.95.2, because `egcs` on DEC has some serious bugs!

When compiling threaded programs under Digital Unix, the documentation recommends using the -`pthread` option for `cc` and `cxx` and the `-lmach -lexc` libraries (in addition to `-lpthread`). You should run `configure` something like this:

```
CC="cc -pthread" CXX="cxx -pthread -O" \
./configure --with-named-thread-libs="-lpthread -lmach -lexc -lc"
```

When compiling `mysqld`, you may see a couple of warnings like this:

```
mysqld.cc: In function void handle_connections()':
mysqld.cc:626: passing long unsigned int *' as argument 3 of
accept(int,sockadddr *, int *)'
```

You can safely ignore these warnings. They occur because `configure` can detect only errors, not warnings.

If you start the server directly from the command line, you may have problems with it dying when you log out. (When you log out, your outstanding processes receive a `SIGHUP` signal.) If so, try starting the server like this:

```
nohup mysqld [options] &
```

`nohup` causes the command following it to ignore any `SIGHUP` signal sent from the terminal. Alternatively, start the server by running `mysqld_safe`, which invokes `mysqld` using `nohup` for you. See Section 5.1.3, "mysqld_safe — MySQL Server Startup Script".

If you get a problem when compiling `mysys/get_opt.c`, just remove the `#define` `_NO_PROTO` line from the start of that file.

If you are using Compaq's CC compiler, the following `configure` line should work:

```
CC="cc -pthread"
CFLAGS="-O4 -ansi_alias -ansi_args -fast -inline speed all -arch host"
CXX="cxx -pthread"
```

```
CXXFLAGS="-O4 -ansi_alias -ansi_args -fast -inline speed all \
    -arch host -noexceptions -nortti"
export CC CFLAGS CXX CXXFLAGS
./configure \
    --prefix=/usr/local/mysql \
    --with-low-memory \
    --enable-large-files \
    --enable-shared=yes \
    --with-named-thread-libs="-lpthread -lmach -lexc -lc"
gnumake
```

If you get a problem with `libtool` when compiling with shared libraries as just shown, when linking `mysql`, you should be able to get around this by issuing these commands:

```
cd mysql
/bin/sh ../libtool --mode=link cxx -pthread  -O3 -DDBUG_OFF \
    -O4 -ansi_alias -ansi_args -fast -inline speed \
    -speculate all \ -arch host  -DUNDEF_HAVE_GETHOSTBYNAME_R \
    -o mysql  mysql.o readline.o sql_string.o completion_hash.o \
    ../readline/libreadline.a -lcurses \
    ../libmysql/.libs/libmysqlclient.so  -lm
cd ..
gnumake
gnumake install
scripts/mysql_install_db
```

2.12.5.6. Alpha-DEC-OSF/1 Notes

If you have problems compiling and have DEC `CC` and `gcc` installed, try running `configure` like this:

```
CC=cc CFLAGS=-O CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql
```

If you get problems with the `c_asm.h` file, you can create and use a 'dummy' `c_asm.h` file with:

```
touch include/c_asm.h
CC=gcc CFLAGS=-I./include \
CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql
```

Note that the following problems with the `ld` program can be fixed by downloading the latest DEC (Compaq) patch kit from: http://ftp.support.compaq.com/public/unix/.

On OSF/1 V4.0D and compiler "DEC C V5.6-071 on Digital Unix V4.0 (Rev. 878)," the compiler had some strange behavior (undefined `asm` symbols). `/bin/ld` also appears to be broken (problems with `_exit undefined` errors occurring while linking `mysqld`). On this system, we have managed to compile MySQL with the following `configure` line, after replacing `/bin/ld` with the version from OSF 4.0C:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
```

With the Digital compiler "C++ V6.1-029," the following should work:

```
CC=cc -pthread
CFLAGS=-O4 -ansi_alias -ansi_args -fast -inline speed \
       -speculate all -arch host
CXX=cxx -pthread
CXXFLAGS=-O4 -ansi_alias -ansi_args -fast -inline speed \
        -speculate all -arch host -noexceptions -nortti
export CC CFLAGS CXX CXXFLAGS
./configure --prefix=/usr/mysql/mysql \
```

```
                    --with-mysqld-ldflags=-all-static --disable-shared \
                    --with-named-thread-libs="-lmach -lexc -lc"
```

In some versions of OSF/1, the `alloca()` function is broken. Fix this by removing the line in `config.h` that defines `'HAVE_ALLOCA'`.

The `alloca()` function also may have an incorrect prototype in `/usr/include/alloca.h`. This warning resulting from this can be ignored.

`configure` uses the following thread libraries automatically: `--with-named-thread-libs="-lpthread -lmach -lexc -lc"`.

When using `gcc`, you can also try running `configure` like this:

```
CFLAGS=-D_PTHREAD_USE_D4 CXX=gcc CXXFLAGS=-O3 ./configure ...
```

If you have problems with signals (MySQL dies unexpectedly under high load), you may have found an OS bug with threads and signals. In this case, you can tell MySQL not to use signals by configuring with:

```
CFLAGS=-DDONT_USE_THR_ALARM \
CXXFLAGS=-DDONT_USE_THR_ALARM \
./configure ...
```

This doesn't affect the performance of MySQL, but has the side effect that you can't kill clients that are "sleeping" on a connection with `mysqladmin kill` or `mysqladmin shutdown`. Instead, the client dies when it issues its next command.

With `gcc` 2.95.2, you may encounter the following compile error:

```
sql_acl.cc:1456: Internal compiler error in `scan_region',
at except.c:2566
Please submit a full bug report.
```

To fix this, you should change to the `sql` directory and do a cut-and-paste of the last `gcc` line, but change `-O3` to `-O0` (or add `-O0` immediately after `gcc` if you don't have any `-O` option on your compile line). After this is done, you can just change back to the top-level directory and run `make` again.

2.12.5.7. SGI Irix Notes

If you are using Irix Version 6.5.3 or newer, `mysqld` is able to create threads only if you run it as a user that has `CAP_SCHED_MGT` privileges (such as `root`) or give the `mysqld` server this privilege with the following shell command:

```
chcap "CAP_SCHED_MGT+epi" /opt/mysql/libexec/mysqld
```

You may have to undefine some symbols in `config.h` after running `configure` and before compiling.

In some Irix implementations, the `alloca()` function is broken. If the `mysqld` server dies on some `SELECT` statements, remove the lines from `config.h` that define `HAVE_ALLOC` and `HAVE_ALLOCA_H`. If `mysqladmin create` doesn't work, remove the line from `config.h` that defines `HAVE_READDIR_R`. You may have to remove the `HAVE_TERM_H` line as well.

SGI recommends that you install all the patches on this page as a set: http://support.sgi.com/surfzone/patches/patchset/6.2_indigo.rps.html

At the very minimum, you should install the latest kernel rollup, the latest `rld` rollup, and the latest `libc` rollup.

You definitely need all the POSIX patches on this page, for pthreads support:

http://support.sgi.com/surfzone/patches/patchset/6.2_posix.rps.html

If you get the something like the following error when compiling `mysql.cc`:

```
"/usr/include/curses.h", line 82: error(1084):
invalid combination of type
```

Type the following in the top-level directory of your MySQL source tree:

```
extra/replace bool curses_bool < /usr/include/curses.h > include/curses.h
make
```

There have also been reports of scheduling problems. If only one thread is running, performance is slow. Avoid this by starting another client. This may lead to a two-to-tenfold increase in execution speed thereafter for the other thread. This is a poorly understood problem with Irix threads; you may have to improvise to find solutions until this can be fixed.

If you are compiling with `gcc`, you can use the following `configure` command:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql --enable-thread-safe-client \
    --with-named-thread-libs=-lpthread
```

On Irix 6.5.11 with native Irix C and C++ compilers ver. 7.3.1.2, the following is reported to work

```
CC=cc CXX=CC CFLAGS='-O3 -n32 -TARG:platform=IP22 -I/usr/local/include \
-L/usr/local/lib' CXXFLAGS='-O3 -n32 -TARG:platform=IP22 \
-I/usr/local/include -L/usr/local/lib' \
./configure --prefix=/usr/local/mysql --with-innodb --with-berkeley-db \
    --with-libwrap=/usr/local \
    --with-named-curses-libs=/usr/local/lib/libncurses.a
```

2.12.5.8. SCO UNIX and OpenServer 5.0.x Notes

The current port is tested only on "sco3.2v5.0.5," "sco3.2v5.0.6," and "sco3.2v5.0.7" systems. There has also been a lot of progress on a port to "sco 3.2v4.2." Open Server 5.0.8(Legend) has native threads and allows files greater than 2GB. The current maximum file size is 2GB.

We have been able to compile MySQL with the following `configure` command on OpenServer with `gcc` 2.95.3.

```
CC=gcc CXX=gcc ./configure --prefix=/usr/local/mysql \
    --enable-thread-safe-client --with-innodb \
    --with-openssl --with-vio --with-extra-charsets=complex
```

`gcc` is available at ftp://ftp.sco.com/pub/openserver5/opensrc/gnutools-5.0.7Kj.

This development system requires the OpenServer Execution Environment Supplement oss646B on OpenServer 5.0.6 and oss656B and The OpenSource libraries found in gwxlibs. All OpenSource tools are in the opensrc directory. They are available at ftp://ftp.sco.com/pub/openserver5/opensrc/.

We recommend using the latest production release of MySQL.

SCO provides operating system patches at ftp://ftp.sco.com/pub/openserver5 for OpenServer 5.0.[0-6] and ftp://ftp.sco.com/pub/openserverv5/507 for OpenServer 5.0.7.

SCO provides information about security fixes at ftp://ftp.sco.com/pub/security/OpenServer for

OpenServer 5.0.x.

The maximum file size on an OpenSever 5.0.x system is 2GB.

The total memory which could be allocated for streams buffers, clists and lock records cannot exceed 60MB on OpenServer 5.0.x.

Streams buffers are allocated in units of 4096 byte pages, clists are 70 bytes each, and lock records are 64 bytes each, so:

```
(NSTRPAGES * 4096) + (NCLIST * 70) + (MAX_FLCKREC * 64) <= 62914560
```

Follow this procedure to configure the Database Services option. If you are unsure whether an application requires this, see the documentation provided with the application.

1. Log in as `root`.

2. Enable the SUDS driver by editing the `/etc/conf/sdevice.d/suds` file. Change the `N` in the second field to a `Y`.

3. Use `mkdev aio` or the Hardware/Kernel Manager to enable support for asynchronous I/O and relink the kernel. To allow users to lock down memory for use with this type of I/O, update the aiomemlock(F) file. This file should be updated to include the names of users that can use AIO and the maximum amounts of memory they can lock down.

4. Many applications use setuid binaries so that you need to specify only a single user. See the documentation provided with the application to see if this is the case for your application.

After you complete this process, reboot the system to create a new kernel incorporating these changes.

By default, the entries in `/etc/conf/cf.d/mtune` are set as follows:

Value	Default	Min	Max
NBUF	0	24	450000
NHBUF	0	32	524288
NMPBUF	0	12	512
MAX_INODE	0	100	64000
MAX_FILE	0	100	64000
CTBUFSIZE	128	0	256
MAX_PROC	0	50	16000

* Shared Memory Parameters
SHMMAX          524288          131072          2147483647
SHMMIN          1               1               1
SHMMNI          100             100             2000
FILE            0               100             64000
NMOUNT          0               4               256
NPROC           0               50              16000
NREGION         0               500             160000
```

We recommend setting these values as follows:

NOFILES should be 4096 or 2048.

MAXUP should be 2048.

To make changes to the kernel, cd to /etc/conf/bin and use ./idtune *name parameter* to make the changes. For example, to change SEMMS to 200, execute these commands as root:

```
# cd /etc/conf/bin
# ./idtune SEMMNS 200
```

We recommend tuning the system, but the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following affects the kernel parameters defined in /etc/conf/cf.d/stune:

SHMMAX (recommended setting: 128MB) and SHMSEG (recommended setting: 15). These parameters have influence on the MySQL database engine to create user buffer pools.

NOFILES and MAXUP should be at to at least 2048.

MAXPROC should be set to at least 3000/4000 (depends on number of users) or more.

Also is recommended to use following formula to count value for SEMMSL, SEMMNS and SEMMNU:

SEMMSL = 13

The 13 is what has been found to be the best for both Progress and MySQL.

SEMMNS = SEMMSL * number of db servers to be run on the system.

Set SEMMNS to the value of SEMMSL multiplied by the number of db servers (maximum) that you are running on the system at one time.

SEMMNU = SEMMNS

Set the value of SEMMNU to equal the value of SEMMNS. You could probably set this to 75% of SEMMNS, but this is a conservative estimate.

You need to at least install the "SCO OpenServer Linker and Application Development Libraries" or the OpenServer Development System to use gcc. You cannot just use the GCC Dev system without

installing one of these.

You should get the FSU Pthreads package and install it first. This can be found at ht-tp://moss.csc.ncsu.edu/~mueller/ftp/pub/PART/pthreads.tar.gz. You can also get a precompiled package from ftp://ftp.zenez.com/pub/zenez/prgms/FSU-threads-3.14.tar.gz.

FSU Pthreads can be compiled with SCO Unix 4.2 with tcpip, or using OpenServer 3.0 or Open Desktop 3.0 (OS 3.0 ODT 3.0) with the SCO Development System installed using a good port of GCC 2.5.x. For ODT or OS 3.0, you need a good port of GCC 2.5.x. There are a lot of problems without a good port. The port for this product requires the SCO Unix Development system. Without it, you are missing the libraries and the linker that is needed. You also need `SCO-3.2v4.2-includes.tar.gz`. This file contains the changes to the SCO Development include files that are needed to get MySQL to build. You need to replace the existing system include files with these modified header files. They can be obtained from ftp://ftp.zenez.com/pub/zenez/prgms/SCO-3.2v4.2-includes.tar.gz.

To build FSU Pthreads on your system, all you should need to do is run GNU `make`. The `Makefile` in FSU-threads-3.14.tar.gz is set up to make FSU-threads.

You can run `./configure` in the `threads/src` directory and select the SCO OpenServer option. This command copies `Makefile.SCO5` to `Makefile`. Then run `make`.

To install in the default `/usr/include` directory, log in as `root`, then `cd` to the `thread/src` directory and run `make install`.

Remember that you must use GNU `make` when making MySQL.

Note: If you don't start `mysqld_safe` as `root`, you should get only the default 110 open files per process. `mysqld` writes a note about this in the log file.

With SCO 3.2V4.2, you should use FSU Pthreads version 3.14 or newer. The following `configure` command should work:

```
CFLAGS="-D_XOPEN_XPG4" CXX=gcc CXXFLAGS="-D_XOPEN_XPG4" \
./configure \
    --prefix=/usr/local/mysql \
    --with-named-thread-libs="-lgthreads -lsocket -lgen -lgthreads" \
    --with-named-curses-libs="-lcurses"
```

You may get some problems with some include files. In this case, you can find new SCO-specific include files at ftp://ftp.zenez.com/pub/zenez/prgms/SCO-3.2v4.2-includes.tar.gz.

You should unpack this file in the `include` directory of your MySQL source tree.

SCO development notes:

- MySQL should automatically detect FSU Pthreads and link `mysqld` with `-lgthreads -lsocket -lgthreads`.

- The SCO development libraries are re-entrant in FSU Pthreads. SCO claims that its library functions are re-entrant, so they must be re-entrant with FSU Pthreads. FSU Pthreads on OpenServer tries to use the SCO scheme to make re-entrant libraries.

- FSU Pthreads (at least the version at ftp://ftp.zenez.com) comes linked with GNU `malloc`. If you encounter problems with memory usage, make sure that `gmalloc.o` is included in `libgthreads.a` and `libgthreads.so`.

- In FSU Pthreads, the following system calls are pthreads-aware: `read()`, `write()`, `getmsg()`, `connect()`, `accept()`, `select()`, and `wait()`.

- The CSSA-2001-SCO.35.2 (the patch is listed in custom as erg711905-dscr_remap security patch (version 2.0.0)) breaks FSU threads and makes `mysqld` unstable. You have to remove this one if you want to run `mysqld` on an OpenServer 5.0.6 machine.

- If you use SCO OpenServer 5, you may need to recompile FSU pthreads with `-DDRAFT7` in `CFLAGS`. Otherwise, `InnoDB` may hang at a `mysqld` startup.

- SCO provides operating system patches at ftp://ftp.sco.com/pub/openserver5 for OpenServer 5.0.x.

- SCO provides security fixes and `libsocket.so.2` at ftp://ftp.sco.com/pub/security/OpenServer and ftp://ftp.sco.com/pub/security/sse for OpenServer 5.0.x.

- Pre-OSR506 security fixes. Also, the `telnetd` fix at ftp://stage.caldera.com/pub/security/openserver/ or ftp://stage.caldera.com/pub/security/openserver/CSSA-2001-SCO.10/ as both `libsocket.so.2` and `libresolv.so.1` with instructions for installing on pre-OSR506 systems.

  It's probably a good idea to install these patches before trying to compile/use MySQL.

Beginning with Legend/OpenServer 6.0.0 has native threads and no 2GB file size limit.

2.12.5.9. SCO UnixWare 7.1.x and OpenUNIX 8.0.0 Notes

We recommend using the latest production release of MySQL. Should you choose to use an older release of MySQL on UnixWare 7.1.x, you must use a version of MySQL at least as recent as 3.22.13 to get fixes for some portability and OS problems.

We have been able to compile MySQL with the following `configure` command on UnixWare Version 7.1.x:

```
CC="cc" CFLAGS="-I/usr/local/include" \
CXX="CC" CXXFLAGS="-I/usr/local/include" \
./configure --prefix=/usr/local/mysql \
    --enable-thread-safe-client --with-berkeley-db=./bdb \
    --with-innodb --with-openssl --with-extra-charsets=complex
```

If you want to use `gcc`, you must use `gcc` 2.95.3 or newer.

```
CC=gcc CXX=g++ ./configure --prefix=/usr/local/mysql
```

The version of Berkeley DB that comes with either UnixWare 7.1.4 or OpenServer 6.0.0 is not used when building MySQL. MySQL instead uses its own version of Berkeley DB. The `configure` command needs to build both a static and a dynamic library in *src_directory*/bdb/build_unix/, but it doesn't with MySQL's own BDB version. The workaround is as follows.

1. Configure as normal for MySQL.

2. `cd bdb/build_unix/`

3. `cp -p Makefile to Makefile.sav`

4. Use same options and run `../dist/configure`.

5. Run `gmake`.

6. `cp -p Makefile.sav Makefile`

7. Change to top source directory and run `gmake`.

This allows both the shared and dynamic libraries to be made and work.

SCO provides operating system patches at ftp://ftp.sco.com/pub/unixware7 for UnixWare 7.1.1, ftp://ftp.sco.com/pub/unixware7/713/ for UnixWare 7.1.3, ftp://ftp.sco.com/pub/unixware7/714/ for UnixWare 7.1.4, and ftp://ftp.sco.com/pub/openunix8 for OpenUNIX 8.0.0.

SCO provides information about security fixes at ftp://ftp.sco.com/pub/security/OpenUNIX for OpenUNIX and ftp://ftp.sco.com/pub/security/UnixWare for UnixWare.

By default, the maximum file size on a UnixWare 7.1.1 system is 1GB, but UnixWare 7.1.4 file size limit is 1 TB with VXFS. Some OS utilities have a limitation of 2GB. The maximum possible file size on UnixWare 7 is 1TB with VXFS.

On UnixWare 7.1.4 you do not need to do anything to get large file support, but to enable large file support on prior versions of UnixWare 7.1.x, run `fsadm`.

```
# fsadm -Fvxfs -o largefiles /
# fsadm /              * Note
# ulimit unlimited
# cd /etc/conf/bin
# ./idtune SFSZLIM 0x7FFFFFFF      ** Note
# ./idtune HFSZLIM 0x7FFFFFFF      ** Note
# ./idbuild -B

* This should report "largefiles".
** 0x7FFFFFFF represents infinity for these values.
```

Reboot the system using `shutdown`.

By default, the entries in `/etc/conf/cf.d/mtune` are set to:

```
Value            Default         Min             Max
-----            -------         ---             ---
SVMMLIM          0x9000000       0x1000000       0x7FFFFFFF
HVMMLIM          0x9000000       0x1000000       0x7FFFFFFF
SSTKLIM          0x1000000       0x2000          0x7FFFFFFF
HSTKLIM          0x1000000       0x2000          0x7FFFFFFF
```

We recommend setting these values as follows:

```
SDATLIM 0x7FFFFFFF
HDATLIM 0x7FFFFFFF
SSTKLIM 0x7FFFFFFF
HSTKLIM 0x7FFFFFFF
SVMMLIM 0x7FFFFFFF
HVMMLIM 0x7FFFFFFF
SFNOLIM 2048
HFNOLIM 2048
```

We recommend tuning the system, but the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following affects the kernel parameters defined in `/etc/conf/cf.d/stune`:

SHMMAX (recommended setting: 128MB) and SHMSEG (recommended setting: 15). These parameters have influence on the MySQL database engine to create user buffer pools.

SFNOLIM and HFNOLIM should be at maximum 2048.

NPROC should be set to at least 3000/4000 (depends on number of users).

Also is recommended to use following formula to count value for SEMMSL, SEMMNS, and SEMMNU:

```
SEMMSL = 13
```

13 is what has been found to be the best for both Progress and MySQL.

SEMMNS = SEMMSL * number of db servers to be run on the system.

Set SEMMNS to the value of SEMMSL multiplied by the number of db servers (maximum) that you are running on the system at one time.

SEMMNU = SEMMNS

Set the value of SEMMNU to equal the value of SEMMNS. You could probably set this to 75% of SEMMNS, but this is a conservative estimate.

2.12.5.10. SCO OpenServer 6.0.x Notes

Key improvements of OpenServer 6 include:

- Larger file support up to 1 TB

- Multiprocessor support increased from 4 to 32 processors

- Increased memory support up to 64 GB

- Extending the power of UnixWare into OpenServer 6

- Dramatic performance improvement

OpenServer 6.0.0 has the following:

- /bin is for commands that behave exactly the same as on OpenServer 5.0.x.

- /u95/bin is for commands that have better standards conformance, for example Large File System (LFS) support.

- /udk/bin is for commands that behave the same as on UnixWare 7.1.4. The default is for the LFS support.

The following is a guide to setting PATH on OpenServer 6. If the user wants the traditional OpenServer 5.0.x then PATH should be /bin first. If the user wants LFS support then the path should be /u95/bin:/bin. If the user want UnixWare 7 support first then the path would be /udk/bin:/u95/bin:/bin:.

We recommend using the latest production release of MySQL. Should you choose to use an older release of MySQL on OpenServer 6.0.x, you must use a version of MySQL at least as recent as 3.22.13 to get fixes for some portability and OS problems.

We have been able to compile MySQL with the following configure command on OpenServer Version 6.0.x:

```
CC="cc" CFLAGS="-I/usr/local/include" \
CXX="CC" CXXFLAGS="-I/usr/local/include" \
./configure --prefix=/usr/local/mysql \
    --enable-thread-safe-client --with-berkeley-db=./bdb \
    --with-innodb --with-openssl --with-extra-charsets=complex \
    --enable-readline
```

If you want to use gcc, you must use gcc 2.95.3 or newer.

```
CC=gcc CXX=g++ ./configure --prefix=/usr/local/mysql
```

The version of Berkeley DB that comes with either UnixWare 7.1.4 or OpenServer 6.0.0 is not used when building MySQL. MySQL instead uses its own version of Berkeley DB. The `configure` command needs to build both a static and a dynamic library in *src_directory*/`bdb/build_unix/`, but it doesn't with MySQL's own BDB version. The workaround is as follows.

1. Configure as normal for MySQL.

2. `cd bdb/build_unix/`

3. `cp -p Makefile to Makefile.sav`

4. Use same options and run `../dist/configure`.

5. Run `gmake`.

6. `cp -p Makefile.sav Makefile`

7. Change to top source directory and run `gmake`.

This allows both the shared and dynamic libraries to be made and work. OpenServer 6.0.0 also needs patches to the MySQL source tree and the patch for `config.guess` applied to `bdb/dist/config.guess`. You can download the patches from ftp://ftp.zenez.com/pub/zenez/prgms/mysql-4.1.12-osr6-patches.tar.gz and from ftp://ftp.zenez.com/pub/zenez/prgms/mysql-4.x.x-osr6-patches. There is a `README` file there to assist.

SCO provides OpenServer 6 operating system patches at ftp://ftp.sco.com/pub/openserver6.

SCO provides information about security fixes at ftp://ftp.sco.com/pub/security/OpenServer.

By default, the maximum file size on a OpenServer 6.0.0 system is 1TB. Some operating system utilities have a limitation of 2GB. The maximum possible file size on UnixWare 7 is 1TB with VXFS or HTFS.

By default, the entries in `/etc/conf/cf.d/mtune` are set to:

```
Value           Default         Min             Max
-----           -------         ---             ---
SVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
HVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
SSTKLIM         0x1000000       0x2000          0x7FFFFFFF
HSTKLIM         0x1000000       0x2000          0x7FFFFFFF
```

We recommend setting these values as follows:

```
SDATLIM 0x7FFFFFFF
HDATLIM 0x7FFFFFFF
SSTKLIM 0x7FFFFFFF
HSTKLIM 0x7FFFFFFF
SVMMLIM 0x7FFFFFFF
HVMMLIM 0x7FFFFFFF
SFNOLIM 2048
HFNOLIM 2048
```

We recommend tuning the system, but the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following affects the kernel parameters defined in `/etc/conf/cf.d/stune`:

`SHMMAX` (recommended setting: 128MB) and `SHMSEG` (recommended setting: 15). These parameters have influence on the MySQL database engine to create user buffer pools.

SFNOLIM and HFNOLIM should be at maximum 2048.

NPROC should be set to at least 3000/4000 (depends on number of users).

Also is recommended to use following formula to count value for SEMMSL, SEMMNS, and SEMMNU:

```
SEMMSL = 13
```

13 is what has been found to be the best for both Progress and MySQL.

SEMMNS = SEMMSL * number of db servers to be run on the system.

Set SEMMNS to the value of SEMMSL multiplied by the number of db servers (maximum) that you are running on the system at one time.

SEMMNU = SEMMNS

Set the value of SEMMNU to equal the value of SEMMNS. You could probably set this to 75% of SEMMNS, but this is a conservative estimate.

2.12.6. OS/2 Notes

MySQL uses quite a few open files. Because of this, you should add something like the following to your CONFIG.SYS file:

```
SET EMXOPT=-c -n -h1024
```

If you don't do this, you may encounter the following error:

```
File 'xxxx' not found (Errcode: 24)
```

When using MySQL with OS/2 Warp 3, FixPack 29 or above is required. With OS/2 Warp 4, Fix-Pack 4 or above is required. This is a requirement of the Pthreads library. MySQL must be installed on a partition with a type that supports long filenames, such as HPFS, FAT32, and so on.

The INSTALL.CMD script must be run from OS/2's own CMD.EXE and may not work with replacement shells such as 4OS2.EXE.

The scripts/mysql-install-db script has been renamed. It is called install.cmd and is a REXX script, which sets up the default MySQL security settings and creates the WorkPlace Shell icons for MySQL.

Dynamic module support is compiled in but not fully tested. Dynamic modules should be compiled using the Pthreads runtime library.

```
gcc -Zdll -Zmt -Zcrtdll=pthrdrtl -I../include -I../regex -I.. \
    -o example udf_example.cc -L../lib -lmysqlclient udf_example.def
mv example.dll example.udf
```

Note: Due to limitations in OS/2, UDF module name stems must not exceed eight characters. Modules are stored in the /mysql2/udf directory; the safe-mysqld.cmd script puts this directory in the BEGINLIBPATH environment variable. When using UDF modules, specified extensions are ignored---it is assumed to be .udf. For example, in Unix, the shared module might be named example.so and you would load a function from it like this:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'example.so';
```

In OS/2, the module would be named example.udf, but you would not specify the module extension:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'example';
```

2.12.7. BeOS Notes

We have in the past talked with some BeOS developers who have said that MySQL is 80% ported to BeOS, but we haven't heard from them in a while.

2.13. Perl Installation Notes

Perl support for MySQL is provided by means of the `DBI/DBD` client interface. The interface requires Perl Version 5.6.0 or later. It *does not work* if you have an older version of Perl.

If you want to use transactions with Perl DBI, you need to have `DBD::mysql` version 1.2216 or newer. Version 2.9003 or newer is recommended.

If you are using the MySQL 4.1 client library, you must use `DBD::mysql` 2.9003 or newer.

As of MySQL 3.22.8, Perl support is no longer included with MySQL distributions. You can obtain the necessary modules from http://search.cpan.org for Unix, or by using the ActiveState `ppm` program on Windows. The following sections describe how to do this.

Perl support for MySQL must be installed if you want to run the MySQL benchmark scripts. See Section 7.1.4, "The MySQL Benchmark Suite".

2.13.1. Installing Perl on Unix

MySQL Perl support requires that you've installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. However, if you installed MySQL from RPM files on Linux, be sure that you've installed the developer RPM. The client programs are in the client RPM, but client programming support is in the developer RPM.

If you want to install Perl support, the files you need can be obtained from the CPAN (Comprehensive Perl Archive Network) at http://search.cpan.org.

The easiest way to install Perl modules on Unix is to use the `CPAN` module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The `DBD::mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default username and password. (The default username is your login name on Unix, and `ODBC` on Windows. The default password is "no password.") If you can't connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

`DBI` requires the `Data::Dumper` module. It may be installed; if not, you should install it before installing `DBI`.

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a DBI distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

    ```
    shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
    ```

    This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

```
shell> cd DBI-VERSION
```

3. Build the distribution and compile everything:

```
shell> perl Makefile.PL
shell> make
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the DBD::mysql installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the DBD::mysql distribution whenever you install a new release of MySQL, particularly if you notice symptoms such as that all your DBI scripts fail after you upgrade MySQL.

If you don't have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: http://servers.digitaldaze.com/extensions/perl/modules.html#modules

Look under the heading "Installing New Modules that Require Locally Installed Modules."

2.13.2. Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL DBD module with ActiveState Perl:

• Get ActiveState Perl from http://www.activestate.com/Products/ActivePerl/ and install it.

• Open a console window (a "DOS window").

• If required, set the HTTP_proxy variable. For example, you might try:

```
set HTTP_proxy=my.proxy.com:3128
```

• Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```

• If you have not previously done so, install DBI:

```
ppm> install DBI
```

• If this succeeds, run the following command:

```
install \
ftp://ftp.de.uu.net/pub/CPAN/authors/id/JWIED/DBD-mysql-1.2212.x86.ppd
```

This procedure should work at least with ActiveState Perl Version 5.6.

If you can't get the procedure to work, you should instead install the MyODBC driver and connect to the MySQL server through ODBC:

```
use DBI;
```

```
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
  die "Got error $DBI::errstr when connecting to $dsn\n";
```

2.13.3. Problems Using the Perl DBI/DBD Interface

If Perl reports that it can't find the `../mysql/mysql.so` module, then the problem is probably that Perl can't locate the shared library `libmysqlclient.so`.

You should be able to fix this by one of the following methods:

- Compile the `DBD::mysql` distribution with `perl Makefile.PL -static -config` rather than `perl Makefile.PL`.

- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).

- Modify the `-L` options used to compile `DBD::mysql` to reflect the actual location of `libmysqlclient.so`.

- On Linux, you can add the pathname of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.

- Add the pathname of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD::mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the pathname of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL aren't both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

You may see the following error from `DBD::mysql` when you run the tests:

```
t/00base............install_driver(mysql) failed:
Can't load '../blib/arch/auto/DBD/mysql/mysql.so' for module DBD::mysql:
../blib/arch/auto/DBD/mysql/mysql.so: undefined symbol:
uncompress at /usr/lib/perl5/5.00503/i586-linux/DynaLoader.pm line 169.
```

This means that you need to include the `-lz` compression library on the link line. That can be done by changing the following line in the file `lib/DBD/mysql/Install.pm`:

```
$sysliblist .= " -lm";
```

Change that line to:

```
$sysliblist .= " -lm -lz";
```

After this, you *must* run `make realclean` and then proceed with the installation from the beginning.

If you want to install DBI on SCO, you have to edit the `Makefile` in DBI-*xxx* and each subdirectory. Note that the following assumes `gcc` 2.95.2 or newer:

```
OLD:                                       NEW:
CC = cc                                    CC = gcc
CCCDLFLAGS = -KPIC -W1,-Bexport            CCCDLFLAGS = -fpic
CCDLFLAGS = -wl,-Bexport                   CCDLFLAGS =

LD = ld                                    LD = gcc -G -fpic
LDDLFLAGS = -G -L/usr/local/lib            LDDLFLAGS = -L/usr/local/lib
LDFLAGS = -belf -L/usr/local/lib           LDFLAGS = -L/usr/local/lib

LD = ld                                    LD = gcc -G -fpic
OPTIMISE = -Od                             OPTIMISE = -O1

OLD:
CCCFLAGS = -belf -dy -w0 -U M_XENIX -DPERL_SCO5 -I/usr/local/include

NEW:
CCFLAGS = -U M_XENIX -DPERL_SCO5 -I/usr/local/include
```

These changes are necessary because the Perl dynaloader does not load the `DBI` modules if they were compiled with `icc` or `cc`.

If you want to use the Perl module on a system that doesn't support dynamic linking (such as SCO), you can generate a static version of Perl that includes `DBI` and `DBD::mysql`. The way this works is that you generate a version of Perl with the `DBI` code linked in and install it on top of your current Perl. Then you use that to build a version of Perl that additionally has the `DBD` code linked in, and install that.

On SCO, you must have the following environment variables set:

```
LD_LIBRARY_PATH=/lib:/usr/lib:/usr/local/lib:/usr/progressive/lib
```

Or:

```
LD_LIBRARY_PATH=/usr/lib:/lib:/usr/local/lib:/usr/ccs/lib:\
    /usr/progressive/lib:/usr/skunk/lib
LIBPATH=/usr/lib:/lib:/usr/local/lib:/usr/ccs/lib:\
    /usr/progressive/lib:/usr/skunk/lib
MANPATH=scohelp:/usr/man:/usr/local1/man:/usr/local/man:\
    /usr/skunk/man:
```

First, create a Perl that includes a statically linked `DBI` module by running these commands in the directory where your `DBI` distribution is located:

```
shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl
```

Then you must install the new Perl. The output of `make perl` indicates the exact `make` command you need to execute to perform the installation. On SCO, this is `make -f Makefile.aperl inst_perl MAP_TARGET=perl`.

Next, use the just-created Perl to create another Perl that also includes a statically linked `DBD::mysql` by running these commands in the directory where your `DBD::mysql` distribution

is located:

```
shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl
```

Finally, you should install this new Perl. Again, the output of `make perl` indicates the command to use.

Chapter 3. MySQL Tutorial

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the "terminal monitor" or just "monitor") is an interactive program that allows you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` option:

```
shell> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If **you** are the administrator, you need to consult other sections of this manual.)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

3.1. Connecting to and Disconnecting from the Server

To connect to the server, you'll usually need to provide a MySQL username when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you'll also need to specify a hostname. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, username, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
Enter password: ********
```

`host` and `user` represent the hostname where your MySQL server is running and the username of your MySQL account. Substitute appropriate values for your setup. The `********` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: ********
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 4.0.14-log

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The prompt tells you that `mysql` is ready for you to enter commands.

Some MySQL installations allow users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing QUIT (or \q) at the
mysql> prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control-D.

Most examples in the following sections assume that you are connected to the server. They indicate
this by the mysql> prompt.

3.2. Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does
not in itself select any database to work with, but that's okay. At this point, it's more important to
find out a little about how to issue queries than to jump right in creating tables, loading data into
them, and retrieving data from them. This section describes the basic principles of entering com-
mands, using several queries you can try out to familiarize yourself with how mysql works.

Here's a simple command that asks the server to tell you its version number and the current date.
Type it in as shown here following the mysql> prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+--------------+--------------+
| VERSION()    | CURRENT_DATE |
+--------------+--------------+
| 3.22.20a-log | 1999-03-19   |
+--------------+--------------+
1 row in set (0.01 sec)
mysql>
```

This query illustrates several things about mysql:

* A command normally consists of an SQL statement followed by a semicolon. (There are some
  exceptions where a semicolon may be omitted. QUIT, mentioned earlier, is one of them. We'll
  get to others later.)

* When you issue a command, mysql sends it to the server for execution and displays the results,
  then prints another mysql> prompt to indicate that it is ready for another command.

* mysql displays query output in tabular form (rows and columns). The first row contains labels
  for the columns. The rows following are the query results. Normally, column labels are the
  names of the columns you fetch from database tables. If you're retrieving the value of an expres-
  sion rather than a table column (as in the example just shown), mysql labels the column using
  the expression itself.

* mysql shows how many rows were returned and how long the query took to execute, which
  gives you a rough idea of server performance. These values are imprecise because they represent
  wall clock time (not CPU or machine time), and because they are affected by factors such as
  server load and network latency. (For brevity, the "rows in set" line is not shown in the remain-
  ing examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here's another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+-------------+---------+
| SIN(PI()/4) | (4+1)*5 |
+-------------+---------+
|    0.707107 |      25 |
+-------------+---------+
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
+--------------+
| VERSION()    |
+--------------+
| 3.22.20a-log |
+--------------+

+---------------------+
| NOW()               |
+---------------------+
| 1999-03-19 00:15:33 |
+---------------------+
```

A command need not be given all on a single line, so lengthy commands that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here's a simple multiple-line statement:

```
mysql> SELECT
    -> USER()
    -> ,
    -> CURRENT_DATE;
+--------------------+--------------+
| USER()             | CURRENT_DATE |
+--------------------+--------------+
| joesmith@localhost | 1999-03-18   |
+--------------------+--------------+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it hasn't seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you don't want to execute a command that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
    -> USER()
    -> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new command.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in:

Prompt	Meaning

`mysql>`	Ready for new command.
`->`	Waiting for next line of multiple-line command.
`'>`	Waiting for next line, collecting a string that begins with a single quote (''').
`">`	Waiting for next line, collecting a string that begins with a double quote ('"').
`` `> ``	Waiting for next line, collecting an identifier that begins with a backtick ('`').
`/*>`	Waiting for next line, collecting rest of /* comment.

The `` `> `` prompt was implemented MySQL 4.0.16. The `/*>` prompt was implemented in MySQL 4.1.12 and 5.0.6.

Multiple-line statements commonly occur by accident when you intend to issue a command on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()
    ->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()
    -> ;
+--------------------+
| USER()             |
+--------------------+
| joesmith@localhost |
+--------------------+
```

The `'>` and `">` prompts occur during string collection. In MySQL, you can write strings surrounded by either ''' or '"' characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `">` prompt, it means that you've entered a line containing a string that begins with a ''' or '"' quote character, but have not yet entered the matching quote that terminates the string. That's fine if you really are entering a multiple-line string, but how likely is that? Not very. More often, the `'>` and `">` prompts indicate that you've inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
    '>
```

If you enter this `SELECT` statement, then press Enter and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string `'Smith` is missing the second quote.)

At this point, what do you do? The simplest thing is to cancel the command. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting! Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
    '> '\c
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new command.

The `` `> `` prompt is similar to the `'>` and `">` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It's important to know what the `'>`, `">`, and `` `> `` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`---including a line containing `QUIT`. This can be quite confusing, especially if you don't know that you need to supply the terminating quote before you can cancel the current command.

3.3. Creating and Using a Database

Once you know how to enter commands, it's time to access a database.

Suppose that you have several pets in your home (your menagerie) and you'd like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to:

- Create a database

- Create a table

- Load data into the table

- Retrieve data from the table in various ways

- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL Web site. It's available in either compressed `tar` format (http://www.mysql.com/Downloads/Contrib/Examples/menagerie.tar.gz) or Zip format (http://www.mysql.com/Downloads/Contrib/Examples/menagerie.zip).

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+----------+
| Database |
+----------+
| mysql    |
| test     |
| tmp      |
+----------+
```

The list of databases is probably different on your machine, but the `mysql` and `test` databases are likely to be among them. The `mysql` database is required because it describes user access privileges. The `test` database is often provided as a workspace for users to try things out.

Note that you may not see all databases if you don't have the `SHOW DATABASES` privilege. See Section 13.5.1.3, "`GRANT` and `REVOKE` Syntax".

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

Note that `USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything

you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a command like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL username assigned to you and `your_client_host` is the host from which you connect to the server.

3.3.1. Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query.)

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this command:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: ********
```

Note that `menagerie` is not your password on the command just shown. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-pmypassword`, not as `-p mypassword`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

3.3.2. Creating a Table

Creating the database is the easy part, but at this point it's empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You'll want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it's not a good thing to store in a database. Age

changes as time passes, which means you'd have to update your records often. Instead, it's better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

• You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you'll soon need to send out birth-day greetings, for that computer-assisted personal touch.)

• You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
    -> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths of those columns need not all be the same, and need not be 20. You can pick any length from 1 to 255, whatever seems most reasonable to you. (If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.)

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It's simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+---------------------+
| Tables in menagerie |
+---------------------+
| pet                 |
+---------------------+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

3.3.3. Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in `'YYYY-MM-DD'` format; this may be different from what you are used to.)

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	
Claws	Gwen	cat	m	1994-03-17	
Buffy	Harold	dog	f	1989-05-13	
Fang	Benny	dog	m	1990-08-27	
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	
Whistler	Gwen	bird		1997-12-09	
Slim	Benny	snake	m	1996-04-29	

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

name	owner	species	sex	birth	death
Whistler	Gwen	bird	\N	1997-12-09	\N

To load the text file `pet.txt` into the `pet` table, use this command:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

Note that if you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
    -> LINES TERMINATED BY '\r\n';
```

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See Section 5.5.4, "Security Issues with `LOAD DATA LOCAL`" for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CRE-ATE TABLE` statement. Suppose that Diane gets a new hamster named Puffball. You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
    -> VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

Note that string and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

3.3.4. Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

`what_to_select` indicates what you want to see. This can be a list of columns, or `*` to indicate "all columns." `which_table` indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it's present, `conditions_to_satisfy` specifies conditions that rows must satisfy to qualify for retrieval.

3.3.4.1. Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
+----------+--------+---------+------+------------+------------+
| name     | owner  | species | sex  | birth      | death      |
+----------+--------+---------+------+------------+------------+
| Fluffy   | Harold | cat     | f    | 1993-02-04 | NULL       |
| Claws    | Gwen   | cat     | m    | 1994-03-17 | NULL       |
| Buffy    | Harold | dog     | f    | 1989-05-13 | NULL       |
| Fang     | Benny  | dog     | m    | 1990-08-27 | NULL       |
| Bowser   | Diane  | dog     | m    | 1979-08-31 | 1995-07-29 |
| Chirpy   | Gwen   | bird    | f    | 1998-09-11 | NULL       |
| Whistler | Gwen   | bird    | NULL | 1997-12-09 | NULL       |
| Slim     | Benny  | snake   | m    | 1996-04-29 | NULL       |
| Puffball | Diane  | hamster | f    | 1999-03-30 | NULL       |
+----------+--------+---------+------+------------+------------+
```

This form of `SELECT` is useful if you want to review your entire table, for example, after you've just loaded it with your initial dataset. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are least a couple of ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
```

However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

The UPDATE changes only the record in question and does not require you to reload the table.

3.3.4.2. Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the WHERE clause from the SELECT statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+--------+-------+---------+------+------------+------------+
| name   | owner | species | sex  | birth      | death      |
+--------+-------+---------+------+------------+------------+
| Bowser | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+-------+---------+------+------------+------------+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as 'bowser', 'BOWSER', etc. The query result is the same.

You can specify conditions on any column, not just name. For example, if you want to know which animals were born after 1998, test the birth column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Puffball | Diane | hamster | f    | 1999-03-30 | NULL  |
+----------+-------+---------+------+------------+-------+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The preceding query uses the AND logical operator. There is also an OR operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL  |
| Slim     | Benny | snake   | m    | 1996-04-29 | NULL  |
+----------+-------+---------+------+------------+-------+
```

AND and OR may be intermixed, although AND has higher precedence than OR. If you use both operators, it's a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
```

```
    -> OR (species = 'dog' AND sex = 'f');
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

3.3.4.3. Selecting Particular Columns

If you don't want to see entire rows from your table, just name the columns in which you're interested, separated by commas. For example, if you want to know when your animals were born, select the name and birth columns:

```
mysql> SELECT name, birth FROM pet;
+----------+------------+
| name     | birth      |
+----------+------------+
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Buffy    | 1989-05-13 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Puffball | 1999-03-30 |
+----------+------------+
```

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
+--------+
| owner  |
+--------+
| Harold |
| Gwen   |
| Harold |
| Benny  |
| Diane  |
| Gwen   |
| Gwen   |
| Benny  |
| Diane  |
+--------+
```

However, notice that the query simply retrieves the owner field from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword DISTINCT:

```
mysql> SELECT DISTINCT owner FROM pet;
+--------+
| owner  |
+--------+
| Benny  |
| Diane  |
| Gwen   |
| Harold |
+--------+
```

You can use a WHERE clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
```

```
    -> WHERE species = 'dog' OR species = 'cat';
+--------+---------+------------+
| name   | species | birth      |
+--------+---------+------------+
| Fluffy | cat     | 1993-02-04 |
| Claws  | cat     | 1994-03-17 |
| Buffy  | dog     | 1989-05-13 |
| Fang   | dog     | 1990-08-27 |
| Bowser | dog     | 1989-08-31 |
+--------+---------+------------+
```

3.3.4.4. Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It's often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an ORDER BY clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
+----------+------------+
| name     | birth      |
+----------+------------+
| Buffy    | 1989-05-13 |
| Bowser   | 1989-08-31 |
| Fang     | 1990-08-27 |
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Slim     | 1996-04-29 |
| Whistler | 1997-12-09 |
| Chirpy   | 1998-09-11 |
| Puffball | 1999-03-30 |
+----------+------------+
```

On character type columns, sorting---like all other comparison operations---is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using the BINARY cast: ORDER BY BINARY col_name.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the DESC keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
+----------+------------+
| name     | birth      |
+----------+------------+
| Puffball | 1999-03-30 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Claws    | 1994-03-17 |
| Fluffy   | 1993-02-04 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Buffy    | 1989-05-13 |
+----------+------------+
```

You can sort on multiple columns, and you can sort columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
    -> ORDER BY species, birth DESC;
+----------+---------+------------+
| name     | species | birth      |
```

```
+----------+---------+------------+
| Chirpy   | bird    | 1998-09-11 |
| Whistler | bird    | 1997-12-09 |
| Claws    | cat     | 1994-03-17 |
| Fluffy   | cat     | 1993-02-04 |
| Fang     | dog     | 1990-08-27 |
| Bowser   | dog     | 1989-08-31 |
| Buffy    | dog     | 1989-05-13 |
| Puffball | hamster | 1999-03-30 |
| Slim     | snake   | 1996-04-29 |
+----------+---------+------------+
```

Note that the DESC keyword applies only to the column name immediately preceding it (birth); it does not affect the species column sort order.

3.3.4.5. Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, compute the difference in the year part of the current date and the birth date, then subtract one if the current date occurs earlier in the calendar year than the birth date. The following query shows, for each pet, the birth date, the current date, and the age in years.

```
mysql> SELECT name, birth, CURDATE(),
    -> (YEAR(CURDATE())-YEAR(birth))
    -> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
+----------+------------+------------+------+
```

Here, YEAR() pulls out the year part of a date and RIGHT() pulls off the rightmost five characters that represent the MM-DD (calendar year) part of the date. The part of the expression that compares the MM-DD values evaluates to 1 or 0, which adjusts the year difference down a year if CURDATE() occurs earlier in the year than birth. The full expression is somewhat ungainly, so an alias (age) is used to make the output column label more meaningful.

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an ORDER BY name clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
    -> (YEAR(CURDATE())-YEAR(birth))
    -> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet ORDER BY name;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
```

```
 | Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
 | Puffball | 1999-03-30 | 2003-08-19 |    4 |
 | Slim     | 1996-04-29 | 2003-08-19 |    7 |
 | Whistler | 1997-12-09 | 2003-08-19 |    5 |
 +----------+------------+------------+------+
```

To sort the output by age rather than name, just use a different ORDER BY clause:

```
mysql> SELECT name, birth, CURDATE(),
    -> (YEAR(CURDATE())-YEAR(birth))
    -> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet ORDER BY age;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
+----------+------------+------------+------+
```

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the death value is NULL. Then, for those with non-NULL values, compute the difference between the death and birth values:

```
mysql> SELECT name, birth, death,
    -> (YEAR(death)-YEAR(birth)) - (RIGHT(death,5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet WHERE death IS NOT NULL ORDER BY age;
+--------+------------+------------+------+
| name   | birth      | death      | age  |
+--------+------------+------------+------+
| Bowser | 1989-08-31 | 1995-07-29 |    5 |
+--------+------------+------------+------+
```

The query uses death IS NOT NULL rather than death <> NULL because NULL is a special value that cannot be compared using the usual comparison operators. This is discussed later. See Section 3.3.4.6, "Working with NULL Values".

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the birth column. MySQL provides several date-part extraction functions, such as YEAR(), MONTH(), and DAYOF-MONTH(). MONTH() is the appropriate function here. To see how it works, run a simple query that displays the value of both birth and MONTH(birth):

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
+----------+------------+--------------+
| name     | birth      | MONTH(birth) |
+----------+------------+--------------+
| Fluffy   | 1993-02-04 |            2 |
| Claws    | 1994-03-17 |            3 |
| Buffy    | 1989-05-13 |            5 |
| Fang     | 1990-08-27 |            8 |
| Bowser   | 1989-08-31 |            8 |
| Chirpy   | 1998-09-11 |            9 |
| Whistler | 1997-12-09 |           12 |
| Slim     | 1996-04-29 |            4 |
| Puffball | 1999-03-30 |            3 |
+----------+------------+--------------+
```

Finding animals with birthdays in the upcoming month is easy, too. Suppose that the current month is April. Then the month value is 4 and you look for animals born in May (month 5) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
+-------+------------+
| name  | birth      |
+-------+------------+
| Buffy | 1989-05-13 |
+-------+------------+
```

There is a small complication if the current month is December. You don't just add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can even write the query so that it works no matter what the current month is. That way you don't have to use a particular month number in the query. DATE_ADD() allows you to add a time interval to a given date. If you add a month to the value of CURDATE(), then extract the month part with MONTH(), the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
    -> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(),INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add 1 to get the next month after the current one (after using the modulo function (MOD) to wrap around the month value to 0 if it is currently 12):

```
mysql> SELECT name, birth FROM pet
    -> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

Note that MONTH returns a number between 1 and 12. And MOD(something,12) returns a number between 0 and 11. So the addition has to be after the MOD(), otherwise we would go from November (11) to January (1).

3.3.4.6. Working with NULL Values

The NULL value can be surprising until you get used to it. Conceptually, NULL means missing value or unknown value and it is treated somewhat differently than other values. To test for NULL, you cannot use the arithmetic comparison operators such as =, <, or <>. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+----------+-----------+----------+----------+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+----------+-----------+----------+----------+
|     NULL |      NULL |     NULL |     NULL |
+----------+-----------+----------+----------+
```

Clearly you get no meaningful results from these comparisons. Use the IS NULL and IS NOT NULL operators instead:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----------+---------------+
| 1 IS NULL | 1 IS NOT NULL |
+-----------+---------------+
|         0 |             1 |
+-----------+---------------+
```

Note that in MySQL, 0 or NULL means false and anything else means true. The default truth value from a boolean operation is 1.

This special treatment of NULL is why, in the previous section, it was necessary to determine which

animals are no longer alive using `death IS NOT NULL` instead of `death <> NULL`.

Two `NULL` values are regarded as equal in a `GROUP BY`.

When doing an `ORDER BY`, `NULL` values are presented first if you do `ORDER BY ... ASC` and last if you do `ORDER BY ... DESC`.

Note that MySQL 4.0.2 to 4.0.10 incorrectly always sorts `NULL` values first regardless of the sort direction.

A common error when working with `NULL` is to assume that it is not possible to insert a zero or an empty string into a column defined as `NOT NULL`, but this is not the case. These are in fact values, whereas `NULL` means "not having a value". You can test this easily enough by using `IS [NOT] NULL` as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----------+---------------+------------+----------------+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----------+---------------+------------+----------------+
|         0 |             1 |          0 |              1 |
+-----------+---------------+------------+----------------+
```

Thus it is entirely possible to insert a zero or empty string into a `NOT NULL` column, as these are `NOT NULL`. See Section A.5.3, "Problems with `NULL` Values".

3.3.4.7. Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as `vi`, `grep`, and `sed`.

SQL pattern matching allows you to use '_' to match any single character and '%' to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. Note that you do not use = or <> when you use SQL patterns; use the `LIKE` or `NOT LIKE` comparison operators instead.

To find names beginning with 'b':

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

To find names ending with 'fy':

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
```

To find names containing a 'w':

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
```

```
+----------+-------+---------+------+-----------+-----------+
```

To find names containing exactly five characters, use five instances of the '_' pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the REGEXP and NOT REGEXP operators (or RLIKE and NOT RLIKE, which are synonyms).

Some characteristics of extended regular expressions are:

- '.' matches any single character.

- A character class '[...]' matches any character within the brackets. For example, '[abc]' matches 'a', 'b', or 'c'. To name a range of characters, use a dash. '[a-z]' matches any letter, whereas '[0-9]' matches any digit.

- '*' matches zero or more instances of the thing preceding it. For example, 'x*' matches any number of 'x' characters, '[0-9]*' matches any number of digits, and '.*' matches any number of anything.

- A REGEXP pattern match succeed if the pattern matches anywhere in the value being tested. (This differs from a LIKE pattern match, which succeeds only if the pattern matches the entire value.)

- To anchor a pattern so that it must match the beginning or end of the value being tested, use '^' at the beginning or '$' at the end of the pattern.

To demonstrate how extended regular expressions work, the LIKE queries shown previously are re-written here to use REGEXP.

To find names beginning with 'b', use '^' to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

Prior to MySQL Version 3.23.4, REGEXP is case sensitive, and the previous query will return no rows. In this case, to match either lowercase or uppercase 'b', use this query instead:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^[bB]';
```

From MySQL 3.23.4 on, if you really want to force a REGEXP comparison to be case sensitive, use the BINARY keyword to make one of the strings a binary string. This query matches only lowercase 'b' at the beginning of a name:

```
mysql> SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with 'fy', use '$' to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
```

To find names containing a 'w', use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+
```

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value like it would be if you used an SQL pattern.

To find names containing exactly five characters, use '^' and '$' to match the beginning and end of the name, and five instances of '.' in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

You could also write the previous query using the '{n}' "repeat-n-times" operator:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

3.3.4.8. Counting Rows

Databases are often used to answer the question, "How often does a certain type of data occur in a table?" For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as "How many rows are in the pet table?" because there is one record per pet. COUNT(*) counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
+----------+
| COUNT(*) |
+----------+
|        9 |
+----------+
```

Earlier, you retrieved the names of the people who owned pets. You can use COUNT() if you want

to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
+--------+----------+
| owner  | COUNT(*) |
+--------+----------+
| Benny  |        2 |
| Diane  |        2 |
| Gwen   |        3 |
| Harold |        2 |
+--------+----------+
```

Note the use of GROUP BY to group together all records for each owner. Without it, all you get is an error message:

```
mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140: Mixing of GROUP columns (MIN(),MAX(),COUNT()...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

COUNT() and GROUP BY are useful for characterizing your data in various ways. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
+---------+----------+
| species | COUNT(*) |
+---------+----------+
| bird    |        2 |
| cat     |        2 |
| dog     |        3 |
| hamster |        1 |
| snake   |        1 |
+---------+----------+
```

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
+------+----------+
| sex  | COUNT(*) |
+------+----------+
| NULL |        1 |
| f    |        4 |
| m    |        4 |
+------+----------+
```

(In this output, NULL indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| bird    | NULL |        1 |
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

You need not retrieve an entire table when you use COUNT(). For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    -> WHERE species = 'dog' OR species = 'cat'
    -> GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
+---------+------+----------+
```

Or, if you wanted the number of animals per sex only for known-sex animals:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    -> WHERE sex IS NOT NULL
    -> GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

3.3.4.9. Using More Than one Table

The pet table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs:

- To contain the pet name so you know which animal each event pertains to.

- A date so you know when the event occurred.

- A field to describe the event.

- An event type field, if you want to be able to categorize events.

Given these considerations, the CREATE TABLE statement for the event table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
    -> type VARCHAR(15), remark VARCHAR(255));
```

As with the pet table, it's easiest to load the initial records by creating a tab-delimited text file containing the information:

name	date	type	remark
Fluffy	1995-05-15	litter	4 kittens, 3 female, 1 male
Buffy	1993-06-23	litter	5 puppies, 2 female, 3 male
Buffy	1994-06-19	litter	3 puppies, 3 female

Chirpy	1999-03-21	vet	needed beak straightened
Slim	1997-08-03	vet	broken rib
Bowser	1991-10-12	kennel	
Fang	1991-10-12	kennel	
Fang	1998-08-28	birthday	Gave him a new chew toy
Claws	1998-03-17	birthday	Gave him a new flea collar
Whistler	1998-12-09	birthday	First birthday

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you've learned from the queries you've run on the pet table, you should be able to perform retrievals on the records in the event table; the principles are the same. But when is the event table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the event table, but to calculate her age on that date you need her birth date, which is stored in the pet table. This means the query requires both tables:

```
mysql> SELECT pet.name,
    -> (YEAR(date)-YEAR(birth)) - (RIGHT(date,5)<RIGHT(birth,5)) AS age,
    -> remark
    -> FROM pet, event
    -> WHERE pet.name = event.name AND type = 'litter';
+--------+------+----------------------------+
| name   | age  | remark                     |
+--------+------+----------------------------+
| Fluffy |    2 | 4 kittens, 3 female, 1 male |
| Buffy  |    4 | 5 puppies, 2 female, 3 male |
| Buffy  |    5 | 3 puppies, 3 female         |
+--------+------+----------------------------+
```

There are several things to note about this query:

- The FROM clause lists two tables because the query needs to pull information from both of them.

- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a name column. The query uses WHERE clause to match up records in the two tables based on the name values.

- Because the name column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the pet table with itself to produce candidate pairs of males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
    -> FROM pet AS p1, pet AS p2
    -> WHERE p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
+--------+------+--------+------+---------+
| name   | sex  | name   | sex  | species |
```

```
+--------+------+--------+------+---------+
| Fluffy | f    | Claws  | m    | cat     |
| Buffy  | f    | Fang   | m    | dog     |
| Buffy  | f    | Bowser | m    | dog     |
+--------+------+--------+------+---------+
```

In this query, we specify aliases for the table name in order to refer to the columns and keep straight which instance of the table each column reference is associated with.

3.4. Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen SHOW DATABASES, which lists the databases managed by the server. To find out which database is currently selected, use the DATABASE() function:

```
mysql> SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| menagerie  |
+------------+
```

If you haven't selected any database yet, the result is NULL (or the empty string before MySQL 4.1.1).

To find out what tables the current database contains (for example, when you're not sure about the name of a table), use this command:

```
mysql> SHOW TABLES;
+---------------------+
| Tables in menagerie |
+---------------------+
| event               |
| pet                 |
+---------------------+
```

If you want to find out about the structure of a table, the DESCRIBE command is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

Field indicates the column name, Type is the data type for the column, NULL indicates whether the column can contain NULL values, Key indicates whether the column is indexed, and Default specifies the column's default value.

If you have indexes on a table, SHOW INDEX FROM tbl_name produces information about them.

3.5. Using `mysql` in Batch Mode

In the previous sections, you used `mysql` interactively to enter queries and view the results. You can also run `mysql` in batch mode. To do this, put the commands you want to run in a file, then tell `mysql` to read its input from the file:

```
shell> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: ********
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the `--force` command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script allows you to avoid retyping it each time you execute it.

- You can generate new queries from existing ones that are similar by copying and editing script files.

- Batch mode can also be useful while you're developing a query, particularly for multiple-line commands or multiple-statement sequences of commands. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.

- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

  ```
  shell> mysql < batch-file | more
  ```

- You can catch the output in a file for further processing:

  ```
  shell> mysql < batch-file > mysql.out
  ```

- You can distribute your script to other people so they can run the commands, too.

- Some situations do not allow for interactive use, for example, when you run a query from a `cron` job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+---------+
| species |
+---------+
```

```
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
+---------+
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the commands that are executed, use `mysql -vvv`.

You can also use scripts from the `mysql` prompt by using the `source` or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

3.6. Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (`article`, `dealer`) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

(In most MySQL installations, you can use the database name `test`).

You can create and populate the example table with these statements:

```
mysql> CREATE TABLE shop (
    -> article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
    -> dealer  CHAR(20)                 DEFAULT ''     NOT NULL,
    -> price   DOUBLE(16,2)             DEFAULT '0.00' NOT NULL,
    -> PRIMARY KEY(article, dealer));
mysql> INSERT INTO shop VALUES
    -> (1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
    -> (3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
mysql> SELECT * FROM shop;
+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0001 | A      |  3.45 |
|    0001 | B      |  3.99 |
|    0002 | A      | 10.99 |
|    0003 | B      |  1.45 |
|    0003 | C      |  1.69 |
|    0003 | D      |  1.25 |
```

```
|     0004 | D       | 19.95 |
+---------+--------+-------+
```

3.6.1. The Maximum Value for a Column

"What's the highest item number?"

```
SELECT MAX(article) AS article FROM shop;
```

```
+---------+
| article |
+---------+
|       4 |
+---------+
```

3.6.2. The Row Holding the Maximum of a Certain Column

"Find number, dealer, and price of the most expensive article."

In standard SQL (and as of MySQL 4.1), this is easily done with a subquery:

```
SELECT article, dealer, price
FROM   shop
WHERE  price=(SELECT MAX(price) FROM shop);
```

In MySQL versions prior to 4.1, just do it in two steps:

1. Get the maximum price value from the table with a SELECT statement.

    ```
    mysql> SELECT MAX(price) FROM shop;
    +------------+
    | MAX(price) |
    +------------+
    |      19.95 |
    +------------+
    ```

2. Using the value 19.95 shown by the previous query to be the maximum article price, write a query to locate and display the corresponding record:

    ```
    mysql> SELECT article, dealer, price
        -> FROM    shop
        -> WHERE   price=19.95;
    +---------+--------+-------+
    | article | dealer | price |
    +---------+--------+-------+
    |    0004 | D      | 19.95 |
    +---------+--------+-------+
    ```

Another solution is to sort all rows descending by price and only get the first row using the MySQL-specific LIMIT clause:

```
SELECT article, dealer, price
FROM   shop
ORDER BY price DESC
LIMIT 1;
```

Note: If there were several most expensive articles, each with a price of 19.95, the LIMIT solution

would show only one of them!

3.6.3. Maximum of Column per Group

"What's the highest price per article?"

```
SELECT article, MAX(price) AS price
FROM   shop
GROUP BY article

+---------+-------+
| article | price |
+---------+-------+
|    0001 |  3.99 |
|    0002 | 10.99 |
|    0003 |  1.69 |
|    0004 | 19.95 |
+---------+-------+
```

3.6.4. The Rows Holding the Group-wise Maximum of a Certain Field

"For each article, find the dealer or dealers with the most expensive price."

In standard SQL (and as of MySQL 4.1), the problem can be solved with a subquery like this:

```
SELECT article, dealer, price
FROM   shop s1
WHERE  price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article);
```

In MySQL versions prior to 4.1, it's best do it in several steps:

1. Get the list of (article,maxprice) pairs.

2. For each article, get the corresponding rows that have the stored maximum price.

This can easily be done with a temporary table and a join:

```
CREATE TEMPORARY TABLE tmp (
       article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
       price   DOUBLE(16,2)             DEFAULT '0.00' NOT NULL);

LOCK TABLES shop READ;

INSERT INTO tmp SELECT article, MAX(price) FROM shop GROUP BY article;

SELECT shop.article, dealer, shop.price FROM shop, tmp
WHERE shop.article=tmp.article AND shop.price=tmp.price;

UNLOCK TABLES;

DROP TABLE tmp;
```

If you don't use a TEMPORARY table, you must also lock the tmp table.

"Can it be done with a single query?"

Yes, but only by using a quite inefficient trick called the "MAX-CONCAT trick":

```
SELECT article,
       SUBSTRING( MAX( CONCAT(LPAD(price,6,'0'),dealer) ), 7) AS dealer,
  0.00+LEFT(       MAX( CONCAT(LPAD(price,6,'0'),dealer) ), 6) AS price
FROM   shop
GROUP BY article;

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0001 | B      |  3.99 |
|    0002 | A      | 10.99 |
|    0003 | C      |  1.69 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

The last example can be made a bit more efficient by doing the splitting of the concatenated column in the client.

3.6.5. Using User Variables

You can use MySQL user variables to remember results without having to store them in temporary variables in the client. See Section 9.3, "User Variables".

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0003 | D      |  1.25 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

3.6.6. Using Foreign Keys

In MySQL 3.23.44 and up, InnoDB tables support checking of foreign key constraints. See Chapter 15, *The InnoDB Storage Engine*. See also Section 1.8.5.5, "Foreign Keys".

A foreign key constraint is not required merely to join two tables. For table types other than In-noDB, it is possible when defining a column to use a REFERENCES *tbl_name(col_name)* clause, which has no actual effect, and *serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table*. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of CHECK to make sure that *col_name* actually exists in *tbl_name* (or even that *tbl_name* itself exists).

- MySQL does not perform any sort of action on *tbl_name* such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no ON DELETE or ON UPDATE behaviour whatsoever. (While you can write an ON DELETE or ON UPDATE clause as part of the REFERENCES clause, it is also ignored.)

- This syntax creates a *column*; it does **not** create any sort of index or key.

- This syntax will cause an error if used in trying to define an InnoDB table.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
```

```
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    name CHAR(60) NOT NULL,
    PRIMARY KEY (id)
);

CREATE TABLE shirt (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
    color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
    owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
    PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+----+---------------------+
| id | name                |
+----+---------------------+
|  1 | Antonio Paz         |
|  2 | Lilliana Angelovska |
+----+---------------------+

SELECT * FROM shirt;
+----+---------+--------+-------+
| id | style   | color  | owner |
+----+---------+--------+-------+
|  1 | polo    | blue   |     1 |
|  2 | dress   | white  |     1 |
|  3 | t-shirt | blue   |     1 |
|  4 | dress   | orange |     2 |
|  5 | polo    | red    |     2 |
|  6 | dress   | blue   |     2 |
|  7 | t-shirt | white  |     2 |
+----+---------+--------+-------+

SELECT s.* FROM person p, shirt s
 WHERE p.name LIKE 'Lilliana%'
   AND s.owner = p.id
   AND s.color <> 'white';

+----+-------+--------+-------+
| id | style | color  | owner |
+----+-------+--------+-------+
|  4 | dress | orange |     2 |
|  5 | polo  | red    |     2 |
|  6 | dress | blue   |     2 |
+----+-------+--------+-------+
```

When used in this fashion, the REFERENCES clause is not displayed in the output of SHOW CRE-

```
ATE TABLE or DESCRIBE:

SHOW CREATE TABLE shirt\G
*************************** 1. row ***************************
Table: shirt
Create Table: CREATE TABLE `shirt` (
`id` smallint(5) unsigned NOT NULL auto_increment,
`style` enum('t-shirt','polo','dress') NOT NULL,
`color` enum('red','blue','orange','white','black') NOT NULL,
`owner` smallint(5) unsigned NOT NULL,
PRIMARY KEY  (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

The use of REFERENCES in this way as a comment or "reminder" in a column definition works with both MyISAM and BerkeleyDB tables.

3.6.7. Searching on Two Keys

An OR using a single key is well optimized, as is the handling of AND.

The one tricky case is that of searching on two different keys combined with OR:

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR  field2_index = '1'
```

This case is optimized from MySQL 5.0.0. See Section 7.2.6, "Index Merge Optimization".

In MySQL 4.0 and up, you can also solve the problem efficiently by using a UNION that combines the output of two separate SELECT statements. See Section 13.2.7.2, "UNION Syntax".

Each SELECT searches only one key and can be optimized:

```
SELECT field1_index, field2_index
    FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
    FROM test_table WHERE field2_index = '1';
```

Prior to MySQL 4.0, you can achieve the same effect by using a TEMPORARY table and separate SELECT statements. This type of optimization is also very good if you are using very complicated queries where the SQL server does the optimizations in the wrong order.

```
CREATE TEMPORARY TABLE tmp
SELECT field1_index, field2_index
    FROM test_table WHERE field1_index = '1';
INSERT INTO tmp
SELECT field1_index, field2_index
    FROM test_table WHERE field2_index = '1';
SELECT * from tmp;
DROP TABLE tmp;
```

This method of solving the problem is in effect a UNION of two queries.

3.6.8. Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
            day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
            (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
        GROUP BY year,month;
```

Which returns:

```
+------+-------+------+
| year | month | days |
+------+-------+------+
| 2000 |    01 |    3 |
| 2000 |    02 |    2 |
+------+-------+------+
```

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

3.6.9. Using `AUTO_INCREMENT`

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
            id MEDIUMINT NOT NULL AUTO_INCREMENT,
            name CHAR(30) NOT NULL,
            PRIMARY KEY (id)
            );
INSERT INTO animals (name) VALUES ('dog'),('cat'),('penguin'),
                                ('lax'),('whale'),('ostrich');
SELECT * FROM animals;
```

Which returns:

```
+----+---------+
| id | name    |
+----+---------+
|  1 | dog     |
|  2 | cat     |
|  3 | penguin |
|  4 | lax     |
|  5 | whale   |
|  6 | ostrich |
+----+---------+
```

You can retrieve the most recent `AUTO_INCREMENT` value with the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. These functions are connection-specific, so their return value is not affected by another connection also doing inserts.

Note: For a multiple-row insert, `LAST_INSERT_ID()`/`mysql_insert_id()` actually returns the `AUTO_INCREMENT` key from the **first** of the inserted rows. This allows multiple-row inserts to be reproduced correctly on other servers in a replication setup.

For `MyISAM` and `BDB` tables you can specify `AUTO_INCREMENT` on a secondary column in a multiple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column)+1 WHERE prefix=given-prefix`. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
            grp ENUM('fish','mammal','bird') NOT NULL,
            id MEDIUMINT NOT NULL AUTO_INCREMENT,
```

```
            name CHAR(30) NOT NULL,
            PRIMARY KEY (grp,id)
            );
INSERT INTO animals (grp,name) VALUES('mammal','dog'),('mammal','cat'),
            ('bird','penguin'),('fish','lax'),('mammal','whale'),
            ('bird','ostrich');
SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

```
+--------+----+---------+
| grp    | id | name    |
+--------+----+---------+
| fish   |  1 | lax     |
| mammal |  1 | dog     |
| mammal |  2 | cat     |
| mammal |  3 | whale   |
| bird   |  1 | penguin |
| bird   |  2 | ostrich |
+--------+----+---------+
```

Note that in this case (when the AUTO_INCREMENT column is part of a multiple-column index), AUTO_INCREMENT values are reused if you delete the row with the biggest AUTO_INCREMENT value in any group. This happens even for MyISAM tables, for which AUTO_INCREMENT values normally are not reused.)

If the AUTO_INCREMENT column is part of multiple indexes, MySQL will generate sequence values using the index that begins with the AUTO_INCREMENT column, if there is one. For example, if the animals table contained indexes PRIMARY KEY (grp, id) and INDEX (id), MySQL would ignore the PRIMARY KEY for generating sequence values. As a result, the table would contain a single sequence, not a sequence per grp value.

3.7. Queries from the Twin Project

At Analytikerna and Lentus, we have been doing the systems and field work for a big research project. This project is a collaboration between the Institute of Environmental Medicine at Karolinska Institutet Stockholm and the Section on Clinical Research in Aging and Psychology at the University of Southern California.

The project involves a screening part where all twins in Sweden older than 65 years are interviewed by telephone. Twins who meet certain criteria are passed on to the next stage. In this latter stage, twins who want to participate are visited by a doctor/nurse team. Some of the examinations include physical and neuropsychological examination, laboratory testing, neuroimaging, psychological status assessment, and family history collection. In addition, data are collected on medical and environmental risk factors.

More information about Twin studies can be found at: http://www.mep.ki.se/twinreg/index_en.html

The latter part of the project is administered with a Web interface written using Perl and MySQL.

Each night all data from the interviews is moved into a MySQL database.

3.7.1. Find All Non-distributed Twins

The following query is used to determine who goes into the second part of the project:

```
SELECT
    CONCAT(p1.id, p1.tvab) + 0 AS tvid,
    CONCAT(p1.christian_name, ' ', p1.surname) AS Name,
    p1.postal_code AS Code,
    p1.city AS City,
    pg.abrev AS Area,
```

```
            IF(td.participation = 'Aborted', 'A', ' ') AS A,
            p1.dead AS dead1,
            l.event AS event1,
            td.suspect AS tsuspect1,
            id.suspect AS isuspect1,
            td.severe AS tsevere1,
            id.severe AS isevere1,
            p2.dead AS dead2,
            l2.event AS event2,
            h2.nurse AS nurse2,
            h2.doctor AS doctor2,
            td2.suspect AS tsuspect2,
            id2.suspect AS isuspect2,
            td2.severe AS tsevere2,
            id2.severe AS isevere2,
            l.finish_date
    FROM
            twin_project AS tp
            /* For Twin 1 */
            LEFT JOIN twin_data AS td ON tp.id = td.id
                    AND tp.tvab = td.tvab
            LEFT JOIN informant_data AS id ON tp.id = id.id
                    AND tp.tvab = id.tvab
            LEFT JOIN harmony AS h ON tp.id = h.id
                    AND tp.tvab = h.tvab
            LEFT JOIN lentus AS l ON tp.id = l.id
                    AND tp.tvab = l.tvab
            /* For Twin 2 */
            LEFT JOIN twin_data AS td2 ON p2.id = td2.id
                    AND p2.tvab = td2.tvab
            LEFT JOIN informant_data AS id2 ON p2.id = id2.id
                    AND p2.tvab = id2.tvab
            LEFT JOIN harmony AS h2 ON p2.id = h2.id
                    AND p2.tvab = h2.tvab
            LEFT JOIN lentus AS l2 ON p2.id = l2.id
                    AND p2.tvab = l2.tvab,
            person_data AS p1,
            person_data AS p2,
            postal_groups AS pg
    WHERE
            /* p1 gets main twin and p2 gets his/her twin. */
            /* ptvab is a field inverted from tvab */
            p1.id = tp.id AND p1.tvab = tp.tvab AND
            p2.id = p1.id AND p2.ptvab = p1.tvab AND
            /* Just the screening survey */
            tp.survey_no = 5 AND
            /* Skip if partner died before 65 but allow emigration (dead=9) */
            (p2.dead = 0 OR p2.dead = 9 OR
             (p2.dead = 1 AND
              (p2.death_date = 0 OR
               (((TO_DAYS(p2.death_date) - TO_DAYS(p2.birthday)) / 365)
                >= 65))))
            AND
            (
            /* Twin is suspect */
            (td.future_contact = 'Yes' AND td.suspect = 2) OR
            /* Twin is suspect - Informant is Blessed */
            (td.future_contact = 'Yes' AND td.suspect = 1
                                    AND id.suspect = 1) OR
            /* No twin - Informant is Blessed */
            (ISNULL(td.suspect) AND id.suspect = 1
                            AND id.future_contact = 'Yes') OR
            /* Twin broken off - Informant is Blessed */
            (td.participation = 'Aborted'
             AND id.suspect = 1 AND id.future_contact = 'Yes') OR
            /* Twin broken off - No inform - Have partner */
            (td.participation = 'Aborted' AND ISNULL(id.suspect)
                                    AND p2.dead = 0))
            AND
```

```
    l.event = 'Finished'
    /* Get at area code */
    AND SUBSTRING(p1.postal_code, 1, 2) = pg.code
    /* Not already distributed */
    AND (h.nurse IS NULL OR h.nurse=00 OR h.doctor=00)
    /* Has not refused or been aborted */
    AND NOT (h.status = 'Refused' OR h.status = 'Aborted'
    OR h.status = 'Died' OR h.status = 'Other')
ORDER BY
    tvid;
```

Some explanations:

- `CONCAT(p1.id, p1.tvab) + 0 AS tvid`

  We want to sort on the concatenated `id` and `tvab` in numerical order. Adding `0` to the result causes MySQL to treat the result as a number.

- column `id`

  This identifies a pair of twins. It is a key in all tables.

- column `tvab`

  This identifies a twin in a pair. It has a value of `1` or `2`.

- column `ptvab`

  This is an inverse of `tvab`. When `tvab` is `1` this is `2`, and vice versa. It exists to save typing and to make it easier for MySQL to optimize the query.

This query demonstrates, among other things, how to do lookups on a table from the same table with a join (`p1` and `p2`). In the example, this is used to check whether a twin's partner died before the age of 65. If so, the row is not returned.

All of the above exist in all tables with twin-related information. We have a key on both `id`,`tvab` (all tables), and `id`,`ptvab` (`person_data`) to make queries faster.

On our production machine (A 200MHz UltraSPARC), this query returns about 150-200 rows and takes less than one second.

The current number of records in the tables used in the query:

Table	Rows
`person_data`	71074
`lentus`	5291
`twin_project`	5286
`twin_data`	2012
`informant_data`	663
`harmony`	381
`postal_groups`	100

3.7.2. Show a Table of Twin Pair Status

Each interview ends with a status code called `event`. The query shown here is used to display a table over all twin pairs combined by event. This indicates in how many pairs both twins are finished, in how many pairs one twin is finished and the other refused, and so on.

```
SELECT
        t1.event,
        t2.event,
        COUNT(*)
FROM
        lentus AS t1,
        lentus AS t2,
        twin_project AS tp
WHERE
        /* We are looking at one pair at a time */
        t1.id = tp.id
        AND t1.tvab=tp.tvab
        AND t1.id = t2.id
        /* Just the screening survey */
        AND tp.survey_no = 5
        /* This makes each pair only appear once */
        AND t1.tvab='1' AND t2.tvab='2'
GROUP BY
        t1.event, t2.event;
```

3.8. Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat \
        "\"%h\",%{%Y%m%d%H%M%S}t,%>s,\"%b\",\"%{Content-Type}o\",  \
        \"%U\",\"%{Referer}i\",\"%{User-Agent}i\""
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

Chapter 4. Using MySQL Programs

This chapter provides a brief overview of the programs provided by MySQL AB and discusses how to specify options when you run these programs. Most programs have options that are specific to their own operation, but the syntax for specifying options is similar for all of them. Later chapters provide more detailed descriptions of individual programs, including which options they recognize.

4.1. Overview of MySQL Programs

MySQL AB provides several types of programs:

- The MYSQL server and server startup scripts:

  - `mysqld` is the MySQL server

  - `mysqld_safe`, `mysql.server`, and `mysqld_multi` are server startup scripts

  - `mysql_install_db` initializes the data directory and the initial databases

  These programs are discussed further in Chapter 5, *Database Administration*.

- Client programs that access the server:

  - `mysql` is a command-line client for executing SQL statements interactively or in batch mode

  - `mysqlcc` (MySQL Control Center) is an interactive graphical tool for executing SQL statements and administration

  - `mysqladmin` is an administrative client

  - `mysqlcheck` performs table maintenance operations

  - `mysqldump` and `mysqlhotcopy` make database backups

  - `mysqlimport` imports data files

  - `mysqlshow` displays information about databases and tables

  These programs are discussed further in Chapter 8, *MySQL Client and Utility Programs*.

- Utility programs that operate independently of the server:

  - `myisamchk` performs table maintenance operations

  - `myisampack` produces compressed, read-only tables

  - `mysqlbinlog` is a tool for processing binary log files

  - `perror` displays error code meanings

  `myisamchk` is discussed further in Chapter 5, *Database Administration*. The other programs are further in Chapter 8, *MySQL Client and Utility Programs*.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for the client programs, and so forth. If you appear to be missing one or more programs, see Chapter 2, *Installing MySQL* for information on types of distributions and what they contain. It may be that you need to install something else.

4.2. Invoking MySQL Programs

To invoke a MySQL program at the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. "`shell>`" represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are $ for `sh` or `bash`, % for `csh` or `tcsh`, and `C:\>` for Windows `command.com` or `cmd.exe`.

```
shell> mysql test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump --user=root personnel
```

Arguments that begin with a dash are option arguments. They typically specify the type of connection a program should make to the server or affect its operational mode. Options have a syntax that is described in Section 4.3, "Specifying Program Options".

Non-option arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first non-option argument as a database name, so the command `mysql test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program understands and describe the meaning of any additional non-option arguments.

Some options are common to a number of programs. The most common of these are the `--host`, `--user`, and `--password` options that specify connection parameters. They indicate the host where the MySQL server is running, and the username and password of your MySQL account. All MySQL client programs understand these options; they allow you to specify which server to connect to and the account to use on that server.

You may find it necessary to invoke MySQL programs using the pathname to the `bin` directory in which they are installed. This is likely to be the case if you get a "program not found" error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the pathname of the `bin` directory to your `PATH` environment variable setting. Then to run a program you need only type its name, not its entire pathname.

Consult the documentation for your command interpreter for instructions on setting your `PATH`. The syntax for setting environment variables is interpreter-specific.

4.3. Specifying Program Options

You can provide options for MySQL programs in several ways:

• On the command line following the program name. This is most common for options that apply to a specific invocation of the program.

• In an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.

• In environment variables. These are useful for options that you want to apply each time the program runs, although in practice option files are used more commonly for this purpose. (Section 5.11.2, "Running Multiple Servers on Unix" discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for both the server and client programs.)

MySQL programs determine which options are given first by examining environment variables, then option files, and then the command line. If an option is specified multiple times, the last occurrence takes precedence. This means that environment variables have the lowest precedence and

command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying the default values for a program's options in an option file. Then you need not type them each time you run the program, but can override the defaults if necessary by using command-line options.

4.3.1. Using Options on the Command Line

Program options specified on the command line follow these rules:

* Options are given after the command name.

* An option argument begins with one dash or two dashes, depending on whether it has a short name or a long name. Many options have both forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display a help message.

* Option names are case sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)

* Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.

* For a long option that takes a value, separate the option name and the value by an '=' sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between. (`-hlocalhost` and `-h localhost` are equivalent.) An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` or as `--password`. In the latter case (with no password value given), the program prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

  ```
  shell> mysql -ptest
  shell> mysql -p test
  ```

  The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

MySQL 4.0 introduced some additional flexibility in the way you specify options. These changes were made in MySQL 4.0.2. Some of them relate to the way you specify options that have "enabled" and "disabled" states, and to the use of options that might be present in one version of MySQL but not another. Those capabilities are discussed in this section. Another change pertains to the way you use options to set program variables. Section 4.3.4, "Using Options to Set Program Variables" discusses that topic further.

Some options control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```
--disable-column-names
--skip-column-names
--column-names=0
```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The "enabled" form of the option may be specified in any of these ways:

```
--column-names
--enable-column-names
--column-names=1
```

Another change to option processing introduced in MySQL 4.0 is that you can use the `--loose` prefix for command-line options. If an option is prefixed by `--loose`, the program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine, at least if all the versions are as recent as 4.0.2. This prefix is particularly useful when you list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that do not recognize the option issue a warning and ignore it. This strategy requires that versions involved be 4.0.2 or later, because earlier versions know nothing of the `--loose` convention.

Another option which may be occasionally useful with `mysql` is the `-e` or `--execute` option, which can be used to pass SQL statements to the server. The statements must be surrounded by (single or double) quotation marks. (However, if you wish to use quoted values within the query, then you should use double quotes for the query, and single quotes for any quoted values within the query.) When this option is used, the statements are executed, and then `mysql` exits to the command shell immediately thereafter.

For example, you can use the following to obtain a list of user accounts:

```
shell> mysql -u root -p -e "SELECT User, Host FROM user" mysql
Enter password: ******
+------+-----------+
| User | Host      |
+------+-----------+
|      | gigan     |
| root | gigan     |
|      | localhost |
| jon  | localhost |
| root | localhost |
+------+-----------+
shell>
```

Note that the name of the `mysql` database was passed as a separate argument. However, the same query could have been executed using `mysql -u root -p -e "SELECT User, Host FROM mysql.user"` from the shell prompt.

Multiple SQL statements may be passed in this way, separated by semicolons:

```
shell> mysql -u root -p --execute="SELECT Name FROM Country WHERE Name LIKE 'AU
Enter password: ******
+-----------+
| Name      |
+-----------+
| Australia |
| Austria   |
+-----------+
+----------+
| COUNT(*) |
```

```
+----------+
|     4079 |
+----------+
```

Note that the long form (`--execute`) must be followed by an equals sign (=).

The `-e` option may also be used to pass commands in an analogous fashion to the `ndb_mgm` management client for MySQL Cluster. See Section 16.3.6, "Safe Shutdown and Restart" for an example.

4.3.2. Using Option Files

MySQL programs can read startup options from option files (also sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program. Option file capability is available from MySQL 3.22 on.

The following programs support option files: `myisamchk`, `myisampack`, `mysql`, `mysql.server`, `mysqladmin`, `mysqlbinlog`, `mysqlcc`, `mysqlcheck`, `mysqld_safe`, `mysqldump`, `mysqld`, `mysqlhotcopy`, `mysqlimport`, and `mysqlshow`.

On Windows, MySQL programs read startup options from the following files:

Filename	Purpose
`WINDIR\my.ini`	Global options
`C:\my.cnf`	Global options
`INSTALLDIR\my.ini`	Global Options
`defaults-extra-file`	The file specified with `--defaults-extra-file=path`, if any

`WINDIR` represents the location of your Windows directory. This is commonly `C:\Windows` or `C:\WinNT`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

`INSTALLDIR` represents the installation directory of MySQL. This is typically the case with MySQL 4.1.5 and higher, when installed using the installation and configuration wizards. See Section 2.3.5.14, "The Location of the my.ini File".

On Unix, MySQL programs read startup options from the following files:

Filename	Purpose
`/etc/my.cnf`	Global options
`$MYSQL_HOME/my.cnf`	Server-specific options
`defaults-extra-file`	The file specified with `--defaults-extra-file=path`, if any
`~/.my.cnf`	User-specific options

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides. This used to be `DATADIR` prior to MySQL version 5.0.3.

If `MYSQL_HOME` is not set and there is a `my.cnf` file in `DATADIR` and there is no `my.cnf` file in `BASEDIR`, `mysqld_safe` sets `MYSQL_HOME` to `DATADIR`. Otherwise, if `MYSQL_HOME` is not set and there is no `my.cnf` in `DATADIR`, then `mysqld_safe` sets `MYSQL_HOME` to `BASEDIR`.

Typically this is `/usr/local/mysql/data` for a binary installation or `/usr/local/var` for a source installation. Note that this is the data directory location that was specified at configuration

time, not the one specified with `--datadir` when `mysqld` starts. Use of `--datadir` at runtime has no effect on where the server looks for option files, because it looks for them before processing any command-line arguments.

MySQL looks for option files in the order just described and reads any that exist. If an option file that you want to use does not exist, create it with a plain text editor. If multiple option files exist, an option specified in a file read later takes precedence over the same option specified in a file read earlier.

Note: On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional, and acts as a security measure.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option.

The syntax for specifying options in an option file is similar to command-line syntax, except that you omit the leading two dashes. For example, `--quick` or `--host=localhost` on the command line should be specified as `quick` or `host=localhost` in an option file. To specify an option of the form `--loose-opt_name` in an option file, write it as `loose-opt_name`.

Empty lines in option files are ignored. Non-empty lines can take any of the following forms:

- `#comment`, `;comment`

  Comment lines start with '#' or ';'. As of MySQL 4.0.14, a '#'-comment can start in the middle of a line as well.

- `[group]`

  `group` is the name of the program or group for which you want to set options. After a group line, any `opt_name` or `set-variable` lines apply to the named group until the end of the option file or another group line is given.

- `opt_name`

  This is equivalent to `--opt_name` on the command line.

- `opt_name=value`

  This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the '=' character, something that is not true on the command line. As of MySQL 4.0.16, you can quote the value with double quotes or single quotes. This is useful if the value contains a '#' comment character or whitespace.

- `set-variable = var_name=value`

  Set the program variable `var_name` to the given value. This is equivalent to `--set-variable=var_name=value` on the command line. Spaces are allowed around the first '=' character but not around the second. This syntax is deprecated as of MySQL 4.0. See Section 4.3.4, "Using Options to Set Program Variables" for more information on setting program variables.

Leading and trailing blanks are automatically deleted from option names and values. You may use the escape sequences '\b', '\t', '\n', '\r', '\\', and '\s' in option values to represent the backspace, tab, newline, carriage return, and space characters.

On Windows, if an option value represents a pathname, you should specify the value using '/' rather than '\' as the pathname separator. If you use '\', you must double it as '\\', because '\' is the escape character in MySQL.

If an option group name is the same as a program name, options in the group apply specifically to that program.

The [client] option group is read by all client programs (but not by mysqld). This allows you to specify options that apply to every client. For example, [client] is the perfect group to use to specify the password that you use to connect to the server. (But make sure that the option file is readable and writable only by yourself, so that other people cannot find out your password.) Be sure not to put an option in the [client] group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

Beginning with MySQL 4.1.11 in the 4.1 series and MySQL 5.0.4 in the 5.0 series, it is possible to use !include directives in option files to include specific files and !includedir to search specific directories for option files. For example, to include the file /home/mydir/myopt.cnf, you can use the following:

```
!include /home/me/myopt.cnf
```

To search the directory /home/mydir for all files ending in .cnf and to read these as option files, you would use:

```
!includedir /home/mydir
```

Note that these options are section-specific. For example, suppose that you were to use something in my.cnf such as the following:

```
[mysqld]
!include /home/mydir/myopt.cnf
```

In such a case, the file myopt.cnf would be processed only for the server, and the !include directive would be ignored by any client applications. However, if you were to use the following:

```
[mysqldump]
!includedir /home/mydir/my-dump-options
```

then the directory /home/mydir/my-dump-options would be checked for option files ending in .cnf by mysqldump only, and not by the server or by any other client applications.

Note: Currently, any files to be found and included using the !includedir directive **must** have filenames ending in .cnf. On Windows, this directive also checks for files with a .ini extension.

As of MySQL 4.0.14, if you want to create option groups that should be read only by one specific mysqld server release series, you can do this by using groups with names of [mysqld-4.0], [mysqld-4.1], and so forth. The following group indicates that the --new option should be used only by MySQL servers with 4.0.x version numbers:

```
[mysqld-4.0]
new
```

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

The preceding option file uses *var_name=value* syntax for the lines that set the key_buffer_size and max_allowed_packet variables. Prior to MySQL 4.0.2, you would need to use set-variable syntax instead (described earlier in this section).

Here is a typical user option file:

```
[client]
# The following password will be sent to all standard MySQL clients
password="my_password"

[mysql]
no-auto-rehash
set-variable = connect_timeout=2

[mysqlhotcopy]
interactive-timeout
```

This option file uses set-variable syntax to set the connect_timeout variable. For MySQL 4.0.2 and up, you can also set the variable using just connect_timeout=2.

If you have a source distribution, you can find sample option files named my-*xxxx*.cnf in the support-files directory. If you have a binary distribution, look in the support-files directory under your MySQL installation directory (typically C:\mysql on Windows or /usr/local/mysql on Unix). On Windows the sample option files may also be located in the MySQL installation directory. Currently there are sample option files for small, medium, large, and very large systems. To experiment with one of these files, copy it to C:\my.cnf on Windows or to .my.cnf in your home directory on Unix.

Note: On Windows, the .cnf option file extension might not be displayed.

All MySQL programs that support option files handle the following command-line options:

- --no-defaults

  Don't read any option files.

- --print-defaults

  Print the program name and all options that it gets from option files.

- --defaults-file=*path_name*

  Use only the given option file. *path_name* is the full pathname to the file.

- --defaults-extra-file=*path_name*

  Read this option file after the global option file but before the user option file. *path_name* is the full pathname to the file.

To work properly, each of these options must immediately follow the command name on the command line, with the exception that --print-defaults may be used immediately after --defaults-file or --defaults-extra-file.

In shell scripts, you can use the my_print_defaults program to parse option files. The following example shows the output that my_print_defaults might produce when asked to show the options found in the [client] and [mysql] groups:

```
shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

Note for developers: Option file handling is implemented in the C client library simply by processing all matching options (that is, options in the appropriate group) before any command-line arguments. This works nicely for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. See the documentation for your preferred interface for details.

4.3.3. Using Environment Variables to Specify Options

To specify an option using an environment variable, set the variable using the syntax appropriate for your comment processor. For example, on Windows or NetWare, you can set the USER variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the MYSQL_TCP_PORT variable. Typical syntax (such as for sh, bash, zsh, etc.) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the export command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For csh and tcsh there are similar issues. When running these shells, use setenv to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately. These settings persist until you log out. To have the settings take effect each time you log in, place the appropriate command or commands in a startup file that your command interpreter reads each time it starts. Typical startup files are AUTOEXEC.BAT for Windows, .bash_profile for bash, or .tcshrc for tcsh. Consult the documentation for your command interpreter for specific details.

Appendix G, *Environment Variables* lists all environment variables that affect MySQL program operation.

4.3.4. Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime. As of MySQL 4.0.2, program variables are set the same way as any other long option that takes a value. For example, mysql has a max_allowed_packet variable that controls the maximum size of its communication buffer. To set the max_allowed_packet variable for mysql to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. Variable values can have a suffix of K, M, or G (either uppercase or lowercase) to indicate units of kilobytes, megabytes, or gigabytes.

In an option file, the variable setting is given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes.

Prior to MySQL 4.0.2, program variable names are not recognized as option names. Instead, use the `--set-variable` option to assign a value to a variable:

```
shell> mysql --set-variable=max_allowed_packet=16777216
shell> mysql --set-variable=max_allowed_packet=16M
```

In an option file, omit the leading dashes:

```
[mysql]
set-variable = max_allowed_packet=16777216
```

Or:

```
[mysql]
set-variable = max_allowed_packet=16M
```

With `--set-variable`, underscores in variable names cannot be given as dashes for versions of MySQL older than 4.0.2.

The `--set-variable` option is still recognized in MySQL 4.0.2 and up, but is deprecated.

Some server variables can be set at runtime. For details, see Section 5.3.3.1, "Dynamic System Variables".

Chapter 5. Database Administration

This chapter covers topics that deal with administering a MySQL installation, such as configuring the server, managing user accounts, and performing backups.

5.1. The MySQL Server and Server Startup Scripts

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that perform setup operations when you install MySQL or that are helper programs to assist you in starting and stopping the server.

This section provides an overview of the server and related programs, and information about server startup scripts. Information about configuring the server itself is given in Section 5.3, "Configuring the MySQL Server".

5.1.1. Overview of the Server-Side Scripts and Utilities

All MySQL programs take many different options. However, every MySQL program provides a `--help` option that you can use to get a description of the program's options. For example, try `mysqld --help`.

You can override default options for all standard programs by specifying options on the command line or in an option file. Section 4.3, "Specifying Program Options".

The following list briefly describes the MySQL server and server-related programs:

- `mysqld`

  The SQL daemon (that is, the MySQL server). To use client programs, this program must be running, because clients gain access to databases by connecting to the server. See Section 5.3, "Configuring the MySQL Server".

- `mysqld-max`

  A version of the server that includes additional features. See Section 5.1.2, "The `mysqld-max` Extended MySQL Server".

- `mysqld_safe`

  A server startup script. `mysqld_safe` attempts to start `mysqld-max` if it exists, and `mysqld` otherwise. See Section 5.1.3, "mysqld_safe — MySQL Server Startup Script".

- `mysql.server`

  A server startup script. This script is used on systems that use run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See Section 5.1.4, "mysql.server — MySQL Server Startup Script".

- `mysqld_multi`

  A server startup script that can start or stop multiple servers installed on the system. See Section 5.1.5, "mysqld_multi — Program for Managing Multiple MySQL Servers".

- `mysql_install_db`

  This script creates the MySQL grant tables with default privileges. It is usually executed only once, when first installing MySQL on a system. See Section 2.9.2, "Unix Post-Installation Procedures".

- `mysql_fix_privilege_tables`

  This script is used after an upgrade install operation, to update the grant tables with any changes that have been made in newer versions of MySQL. See Section 2.10.8, "Upgrading the Grant Tables".

There are several other programs that also are run on the server host:

- `myisamchk`

  A utility to describe, check, optimize, and repair `MyISAM` tables. `myisamchk` is described in Section 5.8.5, "myisamchk — MyISAM Table-Maintenance Utility".

- `make_binary_distribution`

  This program makes a binary release of a compiled MySQL. This could be sent by FTP to `/pub/mysql/upload/` on `ftp.mysql.com` for the convenience of other MySQL users.

- `mysqlbug`

  The MySQL bug reporting script. It can be used to send a bug report to the MySQL mailing list. (You can also visit http://bugs.mysql.com/ to file a bug report online. See Section 1.7.1.3, "How to Report Bugs or Problems".)

5.1.2. The `mysqld-max` Extended MySQL Server

A MySQL-Max server is a version of the `mysqld` MySQL server that has been built to include additional features.

The distribution to use depends on your platform:

- For Windows, MySQL binary distributions include both the standard server (`mysqld.exe`) and the MySQL-Max server (`mysqld-max.exe`), so you need not get a special distribution. Just use a regular Windows distribution, available at http://dev.mysql.com/downloads/. See Section 2.3, "Installing MySQL on Windows".

- For Linux, if you install MySQL using RPM distributions, use the regular `MySQL-server` RPM first to install a standard server named `mysqld`. Then use the `MySQL-Max` RPM to install a server named `mysqld-max`. The `MySQL-Max` RPM presupposes that you have installed the regular server RPM. See Section 2.4, "Installing MySQL on Linux" for more information on the Linux RPM packages.

- All other MySQL-Max distributions contain a single server that is named `mysqld` but that has the additional features included.

You can find the MySQL-Max binaries on the MySQL AB Web site at http://dev.mysql.com/downloads/mysql-4.0.html.

MySQL AB builds the MySQL-Max servers by using the following `configure` options:

- `--with-server-suffix=-max`

  This option adds a `-max` suffix to the `mysqld` version string.

- `--with-innodb`

  This option enables support for the InnoDB storage engine. MySQL-Max servers always include InnoDB support, but this option actually is needed only for MySQL 3.23. From MySQL 4 onwards, InnoDB is included by default in binary distributions, so you do not need a MySQL-Max server merely to obtain InnoDB support.

- `--with-bdb`

  This option enables support for the Berkeley DB (BDB) storage engine.

- `--with-blackhole-storage-engine`

  This option enables support for the `BLACKHOLE` storage engine in MySQL 4.1.11 and newer.

- `USE_SYMDIR`

  This define is enabled to turn on database symbolic link support for Windows. (This applies only before MySQL 4.0. As of MySQL 4.0, symbolic link support is available for all Windows servers, so a Max server is not needed to take advantage of this feature.)

- `--with-ndbcluster`

  This option enables support for the NDB Cluster storage engine in MySQL 4.1.2 and newer. Note that as of MySQL 5.0.3, Cluster is supported on Linux, Solaris, and Mac OS X only.

MySQL-Max binary distributions are a convenience for those who wish to install precompiled programs. If you build MySQL using a source distribution, you can build your own Max-like server by enabling the same features at configuration time that the MySQL-Max binary distributions are built with.

MySQL-Max servers include the BerkeleyDB (BDB) storage engine whenever possible, but not all platforms support BDB.

MySQL-Max servers for Solaris, Mac OS X, and Linux (on most platforms) include support for the NDB Cluster storage engine. Note that the server must be started with the `ndbcluster` option in order to run the server as part of a MySQL Cluster. (For details, see Section 16.4, "MySQL Cluster Configuration".)

The following table shows on which platforms allow MySQL-Max binaries include support for BDB and/or NDB Cluster:

System	BDB Support	NDB Support
AIX 4.3	N	N
HP-UX 11.0	N	N
Linux-Alpha	N	Y
Linux-IA-64	N	N
Linux-Intel	Y	Y
Mac OS X	N	N
NetWare	N	N
SCO OSR5	Y	N
Solaris-SPARC	Y	Y

Solaris-Intel	N	Y
UnixWare	Y	N
Windows NT/2000/XP	Y	N

To find out which storage engines your server supports, issue the following statement:

```
mysql> SHOW ENGINES;
+------------+---------+-----------------------------------------------------
| Engine     | Support | Comment
+------------+---------+-----------------------------------------------------
| MyISAM     | DEFAULT | Default engine as of MySQL 3.23 with great performance
| HEAP       | YES     | Alias for MEMORY
| MEMORY     | YES     | Hash based, stored in memory, useful for temporary tab
| MERGE      | YES     | Collection of identical MyISAM tables
| MRG_MYISAM | YES     | Alias for MERGE
| ISAM       | NO      | Obsolete storage engine, now replaced by MyISAM
| MRG_ISAM   | NO      | Obsolete storage engine, now replaced by MERGE
| InnoDB     | YES     | Supports transactions, row-level locking, and foreign
| INNOBASE   | YES     | Alias for INNODB
| BDB        | YES     | Supports transactions and page-level locking
| BERKELEYDB | YES     | Alias for BDB
| NDBCLUSTER | NO      | Clustered, fault-tolerant, memory-based tables
| NDB        | NO      | Alias for NDBCLUSTER
| EXAMPLE    | NO      | Example storage engine
| ARCHIVE    | NO      | Archive storage engine
| CSV        | NO      | CSV storage engine
+------------+---------+-----------------------------------------------------
16 rows in set (0.02 sec)
```

Before MySQL 4.1.2, SHOW ENGINES is unavailable. Use the following statement instead and check the value of the variable for the storage engine in which you are interested:

```
mysql> SHOW VARIABLES LIKE 'have_%';
+---------------------+-------+
| Variable_name       | Value |
+---------------------+-------+
| have_archive        | NO    |
| have_bdb            | YES   |
| have_compress       | YES   |
| have_crypt          | NO    |
| have_csv            | NO    |
| have_example_engine | NO    |
| have_geometry       | YES   |
| have_innodb         | YES   |
| have_isam           | NO    |
| have_ndbcluster     | NO    |
| have_openssl        | NO    |
| have_query_cache    | YES   |
| have_raid           | NO    |
| have_rtree_keys     | YES   |
| have_symlink        | YES   |
+---------------------+-------+
15 rows in set (0.15 sec)
```

The precise output from these SHOW commands will vary according to the MySQL version used (and the features which are enabled). The values in the second column indicate the server's level of support for each feature, as shown here:

Value	Meaning
YES	The feature is supported and is active.

NO	The feature is not supported.
DISABLED	The feature is supported but has been disabled.

A value of `NO` means that the server was compiled without support for the feature, so it cannot be activated at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the feature, or because not all options required to enable it were given. In the latter case, the `host_name.err` error log file should contain a reason indicating why the option is disabled.

One situation in which you might see `DISABLED` occurs with MySQL 3.23 when the `InnoDB` storage engine is compiled in. In MySQL 3.23, you must supply at least the `innodb_data_file_path` option at runtime to set up the `InnoDB` tablespace. Without this option, `InnoDB` disables itself. See Section 15.3, "`InnoDB` in MySQL 3.23". You can specify configuration options for the `BDB` storage engine, too, but `BDB` does not disable itself if you do not provide them. See Section 14.4.3, "`BDB` Startup Options".

You might also see `DISABLED` for the `InnoDB`, `BDB`, or `ISAM` storage engines if the server was compiled to support them, but was started with the `--skip-innodb`, `--skip-bdb`, or `--skip-isam` options at runtime.

As of Version 3.23, all MySQL servers support `MyISAM` tables, because `MyISAM` is the default storage engine.

5.1.3. mysqld_safe — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix and NetWare. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log file. NetWare-specific behaviors are listed later in this section.

Note: Before MySQL 4.0, `mysqld_safe` is named `safe_mysqld`. To preserve backward compatibility, MySQL binary distributions for some time will include `safe_mysqld` as a symbolic link to `mysqld_safe`.

By default, `mysqld_safe` tries to start an executable named `mysqld-max` if it exists, or `mysqld` otherwise. Be aware of the implications of this behavior:

• On Linux, the `MySQL-Max` RPM relies on this `mysqld_safe` behavior. The RPM installs an executable named `mysqld-max`, which causes `mysqld_safe` to automatically use that executable from that point on.

• If you install a MySQL-Max distribution that includes a server named `mysqld-max`, then upgrade later to a non-Max version of MySQL, `mysqld_safe` still attempts to run the old `mysqld-max` server. If you perform such an upgrade, you should manually remove the old `mysqld-max` server to ensure that `mysqld_safe` runs the new `mysqld` server.

To override the default behavior and specify explicitly which server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See Section 5.3.1, "`mysqld` Command-Line Options".

All options specified to `mysqld_safe` on the command line are passed to `mysqld`. If you want to use any options that are specific to `mysqld_safe` and that `mysqld` doesn't support, do not specify them on the command line. Instead, list them in the `[mysqld_safe]` group of an option file. See Section 4.3.2, "Using Option Files".

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sec-

tions in option files. For backward compatibility, it also reads [`safe_mysqld`] sections, although you should rename such sections to [`mysqld_safe`] when you begin using MySQL 4.0 or later.

`mysqld_safe` supports the following options:

- `--help`

  Display a help message and exit. (New in 5.0.3)

- `--autoclose`

  (NetWare only) On NetWare, `mysqld_safe` provides a screen presence. When you unload (shut down) the `mysqld_safe` NLM, the screen does not by default go away. Instead, it prompts for user input:

  `*<NLM has terminated; Press any key to close the screen>*`

  If you want NetWare to close the screen automatically instead, use the `--autoclose` option to `mysqld_safe`.

- `--basedir=path`

  The path to the MySQL installation directory.

- `--core-file-size=size`

  The size of the core file `mysqld` should be able to create. The option value is passed to `ulimit -c`.

- `--datadir=path`

  The path to the data directory.

- `--defaults-extra-file=path`

  The name of an option file to be read in addition to the usual option files. If given, this option must be first.

- `--defaults-file=path`

  The name of an option file to be read instead of the usual option files. If given, this option must be first.

- `--err-log=path`

  The old form of the `--log-error` option, to be used before MySQL 4.0.

- `--ledir=path`

  The path to the directory containing the `mysqld` program. Use this option to explicitly indicate the location of the server.

- `--log-error=path`

  Write the error log to the given file. See Section 5.10.1, "The Error Log".

- `--mysqld=prog_name`

  The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution.

- `--mysqld-version=suffix`

This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The basename is assumed to be `mysqld`. For example, if you use `--mysqld-version=max`, `mysqld_safe` starts the `mysqld-max` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

- `--nice=priority`

  Use the `nice` program to set the server's scheduling priority to the given value. This option was added in MySQL 4.0.14.

- `--no-defaults`

  Do not read any option files. If given, this option must be first.

- `--open-files-limit=count`

  The number of files `mysqld` should be able to open. The option value is passed to `ulimit -n`. Note that you need to start `mysqld_safe` as `root` for this to work properly!

- `--pid-file=path`

  The path to the process ID file.

- `--port=port_num`

  The port number to use when listening for TCP/IP connections.

- `--socket=path`

  The Unix socket file to use for local connections.

- `--timezone=zone`

  Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name | user_id}`

  Run the `mysqld` server as the user having the name *user_name* or the numeric user ID *user_id*. ("User" in this context refers to a system login account, not a MySQL user listed in the grant tables.)

When executing `mysqld_safe`, the `--defaults-file` or `--defaults-extra-option` must be given first, or the option file will not be used. For example, this command will not use the named option file:

```
mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See Section 2.1.5, "Installation Layouts".) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the directory from which `mysqld_safe` is invoked. For binary distributions, `mysqld_safe` looks under its working directory for `bin`

and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).

- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute pathnames. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, you can specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

Normally, you should not edit the `mysqld_safe` script. Instead, configure `mysqld_safe` by using command-line options or options in the `[mysqld_safe]` section of a `my.cnf` option file. In rare cases, it might be necessary to edit `mysqld_safe` to get it to start the server properly. However, if you do this, your modified version of `mysqld_safe` might be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.

On NetWare, `mysqld_safe` is a NetWare Loadable Module (NLM) that is ported from the original Unix shell script. It does the following:

1. Runs a number of system and option checks.

2. Runs a check on `MyISAM` and `ISAM` tables.

3. Provides a screen presence for the MySQL server.

4. Starts `mysqld`, monitors it, and restarts it if it terminates in error.

5. Sends error messages from `mysqld` to the *host_name*`.err` file in the data directory.

6. Sends `mysqld_safe` screen output to the *host_name*`.safe` file in the data directory.

5.1.4. mysql.server — MySQL Server Startup Script

MySQL distributions on Unix include a script named `mysql.server`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the Mac OS X Startup Item for MySQL.

`mysql.server` can be found in the `support-files` directory under your MySQL installation directory or in a MySQL source tree.

If you use the Linux server RPM package (`MySQL-server-`*VERSION*`.rpm`), the `mysql.server` script will be installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See Section 2.4, "Installing MySQL on Linux" for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. Instructions are provided in Section 2.9.2.2, "Starting and Stopping MySQL Automatically".

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. (For backward compatibility, it also reads `[mysql_server]` sections, although you should rename such sections to `[mysql.server]` when you begin using MySQL 4.0 or later.)

5.1.5. mysqld_multi — Program for Managing Multiple MySQL Servers

`mysqld_multi` is meant for managing several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

The program searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--config-file` option). *N* can be any positive integer. This number is referred to in the following discussion as the option group number, or *GNR*. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the `[mysqld]` group used for starting `mysqld`. (See, for example, Section 2.9.2.2, "Starting and Stopping MySQL Automatically".) However, when using multiple servers it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see Section 5.11, "Running Multiple MySQL Servers on the Same Machine".

To invoke `mysqld_multi`, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|report} [GNR[,GNR] ...]
```

`start`, `stop`, and `report` indicate which operation you want to perform. You can perform the designated operation on a single server or multiple servers, depending on the *GNR* list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each *GNR* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *GNR* for a group named `[mysqld17]` is `17`. To specify a range of numbers, separate the first and last numbers by a dash. The *GNR* value `10-13` represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *GNR* list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups `[mysql8]` and `[mysqld10]` through `[mysqld13]`:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysqld_multi --example
```

`mysqld_multi` supports the following options:

- `--config-file=name`

  Specify the name of an alternative option file. This affects where `mysqld_multi` looks for `[mysqldN]` option groups. Without this option, all options are read from the usual `my.cnf` file. The option does not affect where `mysqld_multi` reads its own options, which are always taken from the `[mysqld_multi]` group in the usual `my.cnf` file.

- `--example`

  Display a sample option file.

- `--help`

  Display a help message and exit.

- `--log=name`

  Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name`

  The `mysqladmin` binary to be used to stop servers.

- `--mysqld=prog_name`

  The `mysqld` binary to be used. Note that you can specify `mysqld_safe` as the value for this option also. The options are passed to `mysqld`. Just make sure that you have the directory where `mysqld` is located in your `PATH` environment variable setting or fix `mysqld_safe`.

- `--no-log`

  Print log information to stdout rather than to the log file. By default, output goes to the log file.

- `--password=password`

  The password of the MySQL account to use when invoking `mysqladmin`. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--silent`

  Disable warnings. This option was added in MySQL 4.1.6.

- `--tcp-ip`

  Connect to each MySQL server via the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only via the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name`

  The username of the MySQL account to use when invoking `mysqladmin`.

-

```
--verbose
```

Be more verbose. This option was added in MySQL 4.1.6.

-
```
--version
```

Display version information and exit.

Some notes about `mysqld_multi`:

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same username and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have many different usernames or passwords for the administrative accounts, you might want to create an account on each server that has the same username and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -proot_password
mysql> GRANT SHUTDOWN ON *.*
    -> TO 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
```

  See Section 5.6.2, "How the Privilege System Works". You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the host part of the account name must allow you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`) Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` "guards" its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault. Please note that the `mysqld_safe` script might require that you start it from a certain place. This means that you might have to change location to a certain directory before running `mysqld_multi`. If you have problems starting, please see the `mysqld_safe` script. Check especially the lines:

```
-----------------------------------------------------------------
MY_PWD=`pwd`
# Check if we are starting this relative (for the binary release)
if test -d $MY_PWD/data/mysql -a -f ./share/mysql/english/errmsg.sys -a \
 -x ./bin/mysqld
-----------------------------------------------------------------
```

  See Section 5.1.3, "mysqld_safe — MySQL Server Startup Script". The test performed by these lines should be successful, or you might encounter problems.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`.

- You might want to use the `--user` option for `mysqld`, but in order to do this you need to run the `mysqld_multi` script as the Unix `root` user. Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

- **Important**: Make sure that the data directory is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix root account for this, unless you *know* what you are doing.

- **Most important**: Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same

data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory *does not* give you extra performance in a threaded system. See Section 5.11, "Running Multiple MySQL Servers on the Same Machine".

The following example shows how you might set up an option file for use with `mysqld_multi`. The first and fifth `[mysqldN]` group were intentionally left out from the example to illustrate that you can have "gaps" in the option file. This gives you more flexibility. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file.

```
# This file should probably be in your home dir (~/.my.cnf)
# or /etc/my.cnf
# Version 2.1 by Jani Tolonen

pid-file   = /usr/local/mysql/var6/hostname.pid6
datadir    = /usr/local/mysql/var6
language   = /usr/local/share/mysql/japanese
user       = jani
```

See Section 4.3.2, "Using Option Files".

5.2. The MySQL Instance Manager

This section discusses use of the MySQL Instance Manager. MySQL Instance Manager (IM) is a daemon running on a TCP/IP port, which serves for monitoring and management of MySQL Database Server instances. MySQL Instance Manager is currently available for unix-like operating systems.

MySQL Instance Manager is included in MySQL distributions from version 5.0.3. MySQL Instance Manager can be used to start and stop the MySQL Server, **even from a remote host**, instead of the mysqld_safe script. MySQL Instance Manager also implements the functionality (and most of the

syntax) of the `mysqld_multi` script. A more detailed description of the MySQL Instance Manager follows.

5.2.1. Starting the MySQL Server with MySQL Instance Manager

Normally, the MySQL Database Server is started with the `mysql.server` script, which usually resides in the `/etc/init.d/` folder. In MySQL 5.0.3 this script invokes `mysqlmanager` (the MySQL Instance Manager binary) to start MySQL. In prior versions of MySQL the `mysqld_safe` script is used for this purpose. Starting from MySQL 5.0.4 the behaviour of the init script was changed again to incorporate both setup schemes. In 5.0.4 the init startup script uses the old scheme (invoking `mysqld_safe`) by default, but one can set the `use_mysqld_safe` variable in the script to `0` (zero) to use the MySQL Instance Manager to start a server.

As of MySQL 5.0.10 the MySQL Instance Manager only reads one configuration and will ignore options and instances defined in any additional configuration files. For details see Section 5.2.4, "MySQL Instance Manager Configuration Files"

Instance Manager behaviour in this case depends on the options given in the MySQL configuration file. If there is no configuration file, the MySQL Instance Manager creates an instance named `mysqld` and attempts to start it with default (compiled-in) configuration values. This means that the IM cannot guess the placement of `mysqld` if it is not installed in the default location. If you have installed the MySQL server in a non-standard location you should use a configuration file.

If there is a configuration file, the IM will parse the configuration file in search of `[mysqld]` sections (E.g. `[mysqld]`, `[mysqld1]`, `[mysqld2]`, etc.) Each such section specifies an instance. At startup the IM will start all found instances. The IM stops all instances at shutdown by default.

Note that there is a special option which is recognized only by the IM called `mysqld-path` (`mysqld-path = <path-to-mysqld-binary>`). Use this variable to let the IM know where the mysqld binary resides. You should also set `basedir` and `datadir` options for the server.

The typical startup/shutdown cycle for a MySQL server with the MySQL Instance Manager enabled is as follows:

- The MySQL Instance Manager is started with `/etc/init.d/mysql` script.

- The MySQL Instance Manager starts all instances and monitors them.

- If a server instance fails the MySQL Instance Manager restarts it.

- If the MySQL Instance Manager is shut down (for instance with the `/etc/init.d/mysql stop` command), all instances are shut down by the MySQL Instance Manager.

5.2.2. Connecting to the MySQL Instance Manager and Creating User Accounts

Communication with the MySQL Instance Manager is handled using the MySQL client-server protocol. As such, you can connect to the IM using the standard `mysql` client program, as well as the MySQL C API. The IM supports the new version of the MySQL client-server protocol, so one should use client tools and libraries distributed along with mysql-4.1 or later.

The IM stores its user information in a password file. Default placement for the password file is `/etc/mysqlmanager.passwd`

Password entries look like the following:

`petr:*35110DC9B4D8140F5DE667E28C72DD2597B5C848`

To generate such an entry one should invoke IM with the `--passwd` option. Then the output can be redirected to the `/etc/mysqlmanager.passwd` file to add a new user. The sample command is given below.

```
./mysqlmanager --passwd >> /etc/mysqlmanager.passwd
Creating record for new user.
Enter user name: mike
Enter password: <password>
Re-type password: <password>
```

The following line is added to `/etc/mysqlmanager.passwd`:

```
mike:*00A51F3F48415C7D4E8908980D443C29C69B60C9
```

If there are no entries in the `/etc/mysqlmanager.passwd` file one cannot connect to the IM.

5.2.3. MySQL Instance Manager Command-Line Options

The MySQL Instance Manager supports a number of command line options. A brief listing is available by executing the `./mysqlmanager --help` command. The following commands are available:

- `--help, -?`

  Display the help message and exit.

- `--bind-address=name`

  Bind address to use for connections.

- `--default-mysqld-path=name`

  Where to look for the MySQL Server binary, if no path was provided in the instance section. Example: `default-mysqld-path = /usr/sbin/mysqld`

- `--defaults-file=file_name`

  Read Instance Manager and MySQL Server settings from the given file. All configuration changes by the Instance Manager will be made to this file. This should be used only as the first option to Instance Manager.

- `--log=name`

  The path to the IM log file. This is used with the `--run-as-service` option.

- `--monitoring-interval=seconds`

  Interval to monitor instances in seconds. Instance manager will try to connect to each of monitored instances to check whether they are alive/not hanging. In the case of a failure IM will perform several (in fact many) attempts to restart the instance. One can disable this behavior for particular instances with the `nonguarded` option in the appropriate instance section. If no value was given, the default of 20 seconds will be used.

- `--passwd, -P`

  Prepare entry for passwd file and exit.

- `--password-file=name`

Look for the Instance Manager users and passwords in this file. The default file is `/etc/mysqlmanager.passwd`.

- `--pid-file=`*name*

  The process ID file to use. By default, this file is named `mysqlmanager.pid`.

- `--port=`*port_num*

  The port number to use for connections. (The efault port number, assigned by IANA, is 2273).

- `--print-defaults`

  Print the current defaults and exit. This should be used only as the first option to Instance Manager.

- `--run-as-service`

  Daemonize and start the angel process. The angel process is simple and unlikely to crash. It will restart the IM itself in case of a failure.

- `--socket=`*name*

  The socket file to use for the connection. By default, the file is named `/tmp/mysqlmanager.sock`.

- `--user=`*name*

  Username to start and run the `mysqlmanager` under. It is recommended to run `mysqlmanager` under the same user account used to run the `mysqld` server.

- `--version, -V`

  Output version information and exit.

5.2.4. MySQL Instance Manager Configuration Files

Instance Manager uses the standard `my.cnf` file. It uses the `[manager]` section to read options for itself and the `[mysqld]` sections to create instances. The `[manager]` section contains any of the options listed above. An example `[manager]` section is shown below:

```
# MySQL Instance Manager options section
[manager]
default-mysqld-path = /usr/local/mysql/libexec/mysqld
socket=/tmp/manager.sock
pid-file=/tmp/manager.pid
password-file = /home/cps/.mysqlmanager.passwd
monitoring-interval = 2
port = 1999
bind-address = 192.168.1.5
```

Prior to MySQL 5.0.10, the MySQL Instance Manager read the same configuration files as the MySQL Server, including `/etc/my.cnf`, `~/.my.cnf`, etc. As of MySQL 5.0.10, the MySQL Instance Manager only reads and manages the `/etc/my.cnf` file (but this can be changed with the `--defaults-file=`*file_name* option).

Instance sections specify options given to each instance at startup. These are mainly common MySQL server options, but there are some IM-specific options:

- `mysqld-path = <path-to-mysqld-binary>`

The path to the `mysqld` server binary.

- `shutdown-delay = seconds`

  A number of seconds IM should wait for the instance to shut down. Default time is 35 seconds. After the delay expires, the IM assumes that the instance is hanging and attempts to kill -9 it. If you use InnoDB with large tables, you should increase this value.

- `nonguarded`

  This option should be set if you want to disable IM monitoring functionality for a certain instance.

Several sample instance sections are given below.

```
[mysqld]
mysqld-path=/usr/local/mysql/libexec/mysqld
socket=/tmp/mysql.sock
port=3307
server_id=1
skip-stack-trace
core-file
skip-bdb
log-bin
log-error
log=mylog
log-slow-queries

[mysqld2]
nonguarded
port=3308
server_id=2
mysqld-path= /home/cps/mysql/trees/mysql-4.1/sql/mysqld
socket      = /tmp/mysql.sock4
pid-file    = /tmp/hostname.pid4
datadir= /home/cps/mysql_data/data_dir1
language=/home/cps/mysql/trees/mysql-4.1/sql/share/english
log-bin
log=/tmp/fordel.log
```

5.2.5. Commands Recognized by the MySQL Instance Manager

Once you've set up a password file for the MySQL Instance Manager and the IM is running, you can connect to it. You can use the `mysql` client tool connect through a standard MySQL API. Below goes the list of commands the MySQL Instance Manager currently accepts, with samples.

- `START INSTANCE <instance_name>`

  This command will attempt to start an instance:

  ```
  mysql> start instance mysqld4;
  Query OK, 0 rows affected (0,00 sec)
  ```

- `STOP INSTANCE <instance_name>`

  This will attempt to stop an instance:

  ```
  mysql> stop instance mysqld4;
  Query OK, 0 rows affected (0,00 sec)
  ```

- SHOW INSTANCES

  Show the names of all loaded instances:

  ```
  mysql> show instances;
  +---------------+---------+
  | instance_name | status  |
  +---------------+---------+
  | mysqld3       | offline |
  | mysqld4       | online  |
  | mysqld2       | offline |
  +---------------+---------+
  3 rows in set (0,04 sec)
  ```

- SHOW INSTANCE STATUS <instance_name>

  Show the status and the version info of selected instance:

  ```
  mysql> show instance status mysqld3;
  +---------------+--------+---------+
  | instance_name | status | version |
  +---------------+--------+---------+
  | mysqld3       | online | unknown |
  +---------------+--------+---------+
  1 row in set (0.00 sec)
  ```

- SHOW INSTANCE OPTIONS <instance_name>

  Show options used by an instance:

  ```
  mysql> show instance options mysqld3;
  +---------------+-----------------------------------------------------+
  | option_name   | value                                               |
  +---------------+-----------------------------------------------------+
  | instance_name | mysqld3                                             |
  | mysqld-path   | /home/cps/mysql/trees/mysql-4.1/sql/mysqld          |
  | port          | 3309                                                |
  | socket        | /tmp/mysql.sock3                                    |
  | pid-file      | hostname.pid3                                       |
  | datadir       | /home/cps/mysql_data/data_dir1/                     |
  | language      | /home/cps/mysql/trees/mysql-4.1/sql/share/english   |
  +---------------+-----------------------------------------------------+
  7 rows in set (0.01 sec)
  ```

- SHOW <instance_name> LOG FILES

  The command provides a listing of all log files used by the instance. The result set contains the path to the log file and the log file size. If no log file path is specified in the configuration file (i.e. log=/var/mysql.log), the IM tries to guess its placement. If the IM is unable to guess the logfile placement you should specify the log file location explicitly.

  ```
  mysql> show mysqld log files;
  +-------------+-----------------------------------+----------+
  | Logfile     | Path                              | Filesize |
  +-------------+-----------------------------------+----------+
  | ERROR LOG   | /home/cps/var/mysql/owlet.err     | 9186     |
  | GENERAL LOG | /home/cps/var/mysql/owlet.log     | 471503   |
  | SLOW LOG    | /home/cps/var/mysql/owlet-slow.log| 4463     |
  +-------------+-----------------------------------+----------+
  3 rows in set (0.01 sec)
  ```

- SHOW   <instance_name>   LOG   {ERROR | SLOW | GENERAL}

```
size[,offset_from_end]
```

This command retrieves a portion of the specified log file. Because most users are interested in the latest log messages, the `size` parameter defines the number of bytes you would like to retrieve starting from the log end. You can retrieve data from the middle of the log file by specifying the optional `offset_from_end` parameter. The following example retrieves 21 bytes of data, starting 23 bytes from the end of the log file and ending 2 bytes from the end of the log file:

```
mysql> show mysqld log general 21, 2;
+----------------------+
| Log                  |
+----------------------+
| using password: YES  |
+----------------------+
1 row in set (0.00 sec)
```

- `SET instance_name.option_name=option_value`

  This commands edits the specified instance's configuration file to change/add instance options. The IM assumes that the configuration file is located at `/etc/my.cnf` (the default configuration file can be overridden with the `--defaults-file=file_name` option). You should check that the file exists and has appropriate permissions.

  ```
  mysql> set mysqld2.port=3322;
  Query OK, 0 rows affected (0.00 sec)
  ```

  Changes made to the configuration file will not take effect until the MySQL server is restarted. In addition, these changes are not stored in the instance manager's local cache of instance settings until a `FLUSH INSTANCES` command is executed.

- `UNSET instance_name.option_name`

  This command removes an option from an instance's configuration file.

  ```
  mysql> unset mysqld2.port;
  Query OK, 0 rows affected (0.00 sec)
  ```

  Changes made to the configuration file will not take effect until the MySQL server is restarted. In addition, these changes are not stored in the instance manager's local cache of instance settings until a `FLUSH INSTANCES` command is executed.

- `FLUSH INSTANCES`

  This command forces IM to reread the configuration file and to refresh internal structures. This command should be performed after editing the configuration file. This command does not restart instances:

  ```
  mysql> flush instances;
  Query OK, 0 rows affected (0.04 sec)
  ```

5.3. Configuring the MySQL Server

This section discusses MySQL server configuration topics:

- Startup options that the server supports

- How to set the server SQL mode

- Server system variables

- Server status variables

5.3.1. `mysqld` Command-Line Options

When you start the `mysqld` server, you can specify program options using any of the methods described in Section 4.3, "Specifying Program Options". The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See Section 4.3.2, "Using Option Files".

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups. An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxx_SERVER]` groups, where `xxxxx` is the name of the application into which the server is embedded.

`mysqld` accepts many command-line options. For a list, execute `mysqld --help`. Before MySQL 4.1.1, `--help` prints the full help message. As of 4.1.1, it prints a brief message; to see the full list, use `mysqld --verbose --help`.

The following list shows some of the most common server options. Additional options are described elsewhere:

- Options that affect security: See Section 5.5.3, "Startup Options for `mysqld` Concerning Security".

- SSL-related options: See Section 5.7.7.6, "SSL Command-Line Options".

- Binary log control options: See Section 5.10.4, "The Binary Log".

- Replication-related options: See Section 6.8, "Replication Startup Options".

- Options specific to particular storage engines: See Section 14.1.1, "`MyISAM` Startup Options", Section 14.4.3, "`BDB` Startup Options", Section 15.5, "`InnoDB` Startup Options".

You can also set the value of a server system variable by using the variable name as an option, as described later in this section.

- `--help, -?`

  Display a short help message and exit. Before MySQL 4.1.1, `--help` displays the full help message. As of 4.1.1, it displays an abbreviated message only. Use both the `--verbose` and `--help` options to see the full message.

- `--allow-suspicious-udfs`

  This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded. This prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. This option was added in MySQL 4.0.24, 4.1.10a, and 5.0.3. See Section 25.2.3.6, "User-defined Function Security Precautions".

- `--ansi`

  Use standard SQL syntax instead of MySQL syntax. See Section 1.8.3, "Running MySQL in ANSI Mode". For more precise control over the server SQL mode, use the `--sql-mode` op-

tion instead.

- `--basedir=path`, `-b path`

The path to the MySQL installation directory. All paths are usually resolved relative to this.

- `--big-tables`

Allow large result sets by saving all temporary sets in files. This option prevents most "table full" errors, but also slows down queries for which in-memory tables would suffice. Since MySQL 3.23.2, the server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk tables where necessary.

- `--bind-address=IP`

The IP address to bind to.

- `--bootstrap`

This option is used by the `mysql_install_db` script to create the MySQL privilege tables without having to start a full MySQL server.

- `--console`

Write the error log messages to stderr/stdout even if `--log-error` is specified. On Windows, `mysqld` does not close the console screen if this option is used.

- `--character-sets-dir=path`

The directory where character sets are installed. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--chroot=path`

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure as of MySQL 4.0. (MySQL 3.23 is not able to provide a `chroot()` jail that is 100% closed.) Note that use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- `--character-set-server=charset`

Use `charset` as the default server character set. This option is available as of MySQL 4.1.3. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--core-file`

Write a core file if `mysqld` dies. For some systems, you must also specify the `--core-file-size` option to `mysqld_safe`. See Section 5.1.3, "mysqld_safe — MySQL Server Startup Script". Note that on some systems, such as Solaris, you do not get a core file if you are also using the `--user` option.

- `--collation-server=collation`

Use `collation` as the default server collation. This option is available as of MySQL 4.1.3. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--datadir=path`, `-h path`

The path to the data directory.

- `--debug[=debug_options]`,`-# [debug_options]`

If MySQL is configured with `--with-debug`, you can use this option to get a trace file of what `mysqld` is doing. The `debug_options` string often is `'d:t:o,file_name'`. See

Section F.1.2, "Creating Trace Files".

- `--default-character-set=`*`charset`*

  Use *`charset`* as the default character set. This option is deprecated in favor of `--character-set-server` as of MySQL 4.1.3. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--default-collation=`*`collation`*

  Use *`collation`* as the default collation. This option is deprecated in favor of `--collation-server` as of MySQL 4.1.3. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--default-storage-engine=`*`type`*

  This option is a synonym for `--default-table-type`. It is available as of MySQL 4.1.2.

- `--default-table-type=`*`type`*

  Set the default table type for tables. See Chapter 14, *MySQL Storage Engines and Table Types*.

- `--default-time-zone=`*`type`*

  Set the default server time zone. This option sets the global `time_zone` system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` system variable. This option is available as of MySQL 4.1.3.

- `--delay-key-write[= OFF | ON | ALL]`

  How the `DELAYED KEYS` option should be used. Delayed key writing causes key buffers not to be flushed between writes for `MyISAM` tables. `OFF` disables delayed key writes. `ON` enables delayed key writes for those tables that were created with the `DELAYED KEYS` option. `ALL` delays key writes for all `MyISAM` tables. Available as of MySQL 4.0.3. See Section 7.5.2, "Tuning Server Parameters". See Section 14.1.1, "`MyISAM` Startup Options".

  Note: If you set this variable to `ALL`, you should not use `MyISAM` tables from within another program (such as from another MySQL server or with `myisamchk`) when the table is in use. Doing so leads to index corruption.

- `--delay-key-write-for-all-tables`

  Old form of `--delay-key-write=ALL` for use prior to MySQL 4.0.3. As of 4.0.3, use `--delay-key-write` instead.

- `--des-key-file=`*`file_name`*

  Read the default keys used by `DES_ENCRYPT()` and `DES_DECRYPT()` from this file.

- `--enable-named-pipe`

  Enable support for named pipes. This option applies only on Windows NT, 2000, XP, and 2003 systems, and can be used only with the `mysqld-nt` and `mysqld-max-nt` servers that support named pipe connections.

- `--exit-info[=`*`flags`*`]`,`-T [`*`flags`*`]`

  This is a bit mask of different flags you can use for debugging the `mysqld` server. Do not use this option unless you know exactly what it does!

- `--external-locking`

  Enable system locking. Note that if you use this option on a system on which `lockd` does not fully work (as on Linux), it is easy for `mysqld` to deadlock. This option previously was named

`--enable-locking`.

Note: If you use this option to enable updates to `MyISAM` tables from many MySQL processes, you have to ensure that these conditions are satisfied:

- You should not use the query cache for queries that use tables that are updated by another process.

- You should not use `--delay-key-write=ALL` or `DELAY_KEY_WRITE=1` on any shared tables.

The easiest way to ensure this is to always use `--external-locking` together with `--delay-key-write=OFF --query-cache-size=0`.

(This is not done by default because in many setups it's useful to have a mixture of the above options.)

- `--flush`

Flush all changes to disk after each SQL statement. Normally MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synching to disk. See Section A.4.2, "What to Do If MySQL Keeps Crashing".

- `--init-file=`*`file`*

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

- `--innodb-safe-binlog`

Adds consistency guarantees between the content of `InnoDB` tables and the binary log. See Section 5.10.4, "The Binary Log".

- `--language=`*`lang_name`*`, -L `*`lang_name`*

Client error messages in given language. *`lang_name`* can be given as the language name or as the full pathname to the directory where the language files are installed. See Section 5.9.2, "Setting the Error Message Language".

- `--large-pages`

Some hardware/operating system architectures support memory pages greater than the default (usually 4 KB). The actual implementation of this support depends on the underlying hardware and OS. Applications that perform a lot of memory access may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

Currently, MySQL supports only the Linux implementation of large pages support (which is called HugeTLB in Linux). We have plans to extend this support to FreeBSD, Solaris and possibly other platforms.

Before large pages can be used on Linux, it is necessary to configure the HugeTLB memory pool. For reference, consult the `hugetlbpage.txt` file in the Linux kernel source.

This option is disabled by default. It was added in MySQL 5.0.3.

- `--log[=`*`file`*`],-l [`*`file`*`]`

Log connections and queries to this file. See Section 5.10.2, "The General Query Log". If you don't specify a filename, MySQL uses *`host_name`*`.log` as the filename.

- `--log-bin=[`*`file`*`]`

The binary log file. Log all queries that change data to this file. Used for backup and replication. See Section 5.10.4, "The Binary Log". It is recommended to specify a filename (see Sec-

tion A.8.4, "Open Issues in MySQL" for the reason) otherwise MySQL uses `host_name-bin` as the log file basename.

- `--log-bin-index[=file]`

  The index file for binary log filenames. See Section 5.10.4, "The Binary Log". If you don't specify a filename, and if you didn't specify one in `--log-bin`, MySQL uses `host_name-bin.index` as the filename.

- `--log-bin-trust-routine-creators[={0|1}]`

  With no argument or an argument of 1, this option sets the `log_bin_trust_routine_creators` system variable to 1. With an argument of 0, this option sets the system variable to 0. `log_bin_trust_routine_creators` affects how MySQL enforces restrictions on stored routine creation. See Section 18.4, "Binary Logging of Stored Routines and Triggers".

  This option was added in MySQL 5.0.6.

- `--log-error[=file]`

  Log errors and startup messages to this file. See Section 5.10.1, "The Error Log". If you don't specify a filename, MySQL uses `host_name.err` as the filename. If the filename has no extension, an extension of `.err` is added to the name.

- `--log-isam[=file]`

  Log all `ISAM`/`MyISAM` changes to this file (used only when debugging `ISAM`/`MyISAM`).

- `--log-long-format`

  Log some extra information to the log files (update log, binary update log, and slow queries log, whatever log has been activated). For example, username and timestamp are logged for queries. Before MySQL 4.1, if you are using `--log-slow-queries` and `--log-long-format`, queries that are not using indexes also are logged to the slow query log. `--log-long-format` is deprecated as of MySQL version 4.1, when `--log-short-format` was introduced. (Long log format is the default setting since version 4.1.) Also note that starting with MySQL 4.1, the `--log-queries-not-using-indexes` option is available for the purpose of logging queries that do not use indexes to the slow query log.

- `--log-queries-not-using-indexes`

  If you are using this option with `--log-slow-queries`, then queries that are not using indexes also are logged to the slow query log. This option is available as of MySQL 4.1. See Section 5.10.5, "The Slow Query Log".

- `--log-short-format`

  Log less information to the log files (update log, binary update log, and slow queries log, whatever log has been activated). For example, username and timestamp are not logged for queries. This option was introduced in MySQL 4.1.

- `--log-slow-admin-statements`

  Log slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` to the slow query log.

  This option was added in MySQL 4.1.13. (It is unnecessary in MySQL 4.0 because slow administrative statements are logged by default.)

- `--log-slow-queries[=file]`

  Log all queries that have taken more than `long_query_time` seconds to execute to this file.

See Section 5.10.5, "The Slow Query Log". Note that the default for the amount of information logged has changed in MySQL 4.1. See the `--log-long-format` and `--log-short-format` options for details.

- `--log-update[=file]`

  Log updates to `fileN` where `N` is a unique number if not given. See Section 5.10.3, "The Update Log". The update log is deprecated and is removed in MySQL 5.0.0; you should use the binary log instead (`--log-bin`). See Section 5.10.4, "The Binary Log". Starting from version 5.0.0, using `--log-update` turns on the binary log instead (see Section E.1.14, "Changes in release 5.0.0 (22 Dec 2003: Alpha)").

- `--log-warnings, -W`

  Print out warnings such as `Aborted connection...` to the error log. Enabling this option is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). This option is enabled by default as of MySQL 4.0.19 and 4.1.2; to disable it, use `--skip-log-warnings`. As of MySQL 4.0.21 and 4.1.3, aborted connections are not logged to the error log unless the value is greater than 1. See Section A.2.10, "Communication Errors and Aborted Connections".

  This option was named `--warnings` before MySQL 4.0.

- `--low-priority-updates`

  Table-modifying operations (`INSERT`, `REPLACE`, `DELETE`, `UPDATE`) have lower priority than selects. This can also be done via {`INSERT` | `REPLACE` | `DELETE` | `UPDATE`} `LOW_PRIORITY` ... to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. See Section 7.3.2, "Table Locking Issues".

- `--memlock`

  Lock the `mysqld` process in memory. This works on systems such as Solaris that support the `mlockall()` system call. This might help if you have a problem where the operating system is causing `mysqld` to swap on disk. Note that use of this option requires that you run the server as `root`, which is normally not a good idea for security reasons.

- `--myisam-recover [=option[,option...]]]`

  Set the `MyISAM` storage engine recovery mode. The option value is any combination of the values of `DEFAULT`, `BACKUP`, `FORCE`, or `QUICK`. If you specify multiple values, separate them by commas. You can also use a value of `""` to disable this option. If this option is used, `mysqld`, when it opens a `MyISAM` table, checks whether the table is marked as crashed or wasn't closed properly. (The last option works only if you are running with `--skip-external-locking`.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

  The following options affect how the repair works:

Option	Description
DEFAULT	The same as not giving any option to `--myisam-recover`.
BACKUP	If the data file was changed during recovery, save a backup of the `tbl_name`.MYD file as `tbl_name-datetime`.BAK.
FORCE	Run recovery even if we would lose more than one row from the `.MYD` file.
QUICK	Don't check the rows in the table if there aren't any delete blocks.

Before a table is automatically repaired, MySQL adds a note about this in the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP,FORCE`. This forces a repair of a table even if some rows would be deleted, but

it keeps the old data file as a backup so that you can later examine what happened.

This option is available as of MySQL 3.23.25.

- `--ndb-connectstring=`*`connect_string`*

When using the `NDB` storage engine, it is possible to point out the management server that distributes the cluster configuration by setting the connect string option. See Section 16.4.4.2, "The MySQL Cluster `connectstring`" for syntax.

- `--ndbcluster`

If the binary includes support for the `NDB Cluster` storage engine (from version 4.1.3, the MySQL-Max binaries are built with `NDB Cluster` enabled) the default disabling of support for the `NDB Cluster` storage engine can be overruled by using this option. Using the `NDB Cluster` storage engine is necessary for using MySQL Cluster. See Chapter 16, *MySQL Cluster*.

- `--new`

The `--new` option can be used to make the server behave as 4.1 in certain respects, easing a 4.0 to 4.1 upgrade:

  - Hexadecimal strings such as `0xFF` are treated as strings by default rather than as numbers. (Works in 4.0.12 and up.)

  - `TIMESTAMP` is returned as a string with the format `'YYYY-MM-DD HH:MM:SS'`. (Works in 4.0.13 and up.) See Chapter 11, *Column Types*.

This option can be used to help you see how your applications behave in MySQL 4.1, without actually upgrading to 4.1.

- `--old-passwords`

Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See Section 5.6.9, "Password Hashing in MySQL 4.1".

- `--old-protocol, -o`

Use the 3.20 protocol for compatibility with some very old clients. See Section 2.10.7, "Upgrading from Version 3.20 to 3.21".

- `--one-thread`

Only use one thread (for debugging under Linux). This option is available only if the server is built with debugging enabled. See Section F.1, "Debugging a MySQL Server".

- `--open-files-limit=`*`count`*

To change the number of file descriptors available to `mysqld`. If this is not set or set to 0, then `mysqld` uses this value to reserve file descriptors to use with `setrlimit()`. If this value is 0 then `mysqld` reserves `max_connections*5` or `max_connections + table_cache*2` (whichever is larger) number of files. You should try increasing this if `mysqld` gives you the error "Too many open files."

- `--pid-file=`*`path`*

The path to the process ID file used by `mysqld_safe`.

- `--port=`*`port_num`*`, -P `*`port_num`*

The port number to use when listening for TCP/IP connections.

- `--safe-mode`

  Skip some optimization stages.

- `--safe-show-database`

  With this option, the SHOW DATABASES statement displays only the names of those databases for which the user has some kind of privilege. As of MySQL 4.0.2, this option is deprecated and doesn't do anything (it is enabled by default), because there is a SHOW DATABASES privilege that can be used to control access to database names on a per-account basis. See Section 5.6.3, "Privileges Provided by MySQL".

- `--safe-user-create`

  If this is enabled, a user can't create new users with the GRANT statement, if the user doesn't have the INSERT privilege for the mysql.user table or any column in the table.

- `--secure-auth`

  Disallow authentication for accounts that have old (pre-4.1) passwords. This option is available as of MySQL 4.1.1.

- `--shared-memory`

  Enable shared-memory connections by local clients. This option is available only on Windows. It was added in MySQL 4.1.0.

- `--shared-memory-base-name=name`

  The name to use for shared-memory connections. This option is available only on Windows. It was added in MySQL 4.1.0.

- `--skip-bdb`

  Disable the BDB storage engine. This saves memory and might speed up some operations. Do not use this option if you require BDB tables.

- `--skip-concurrent-insert`

  Turn off the ability to select and insert at the same time on MyISAM tables. (This is to be used only if you think you have found a bug in this feature.)

- `--skip-delay-key-write`

  Ignore the DELAY_KEY_WRITE option for all tables. As of MySQL 4.0.3, you should use --delay-key-write=OFF instead. See Section 7.5.2, "Tuning Server Parameters".

- `--skip-external-locking`

  Don't use system locking. To use isamchk or myisamchk, you must shut down the server. See Section 1.4.3, "MySQL Stability". In MySQL 3.23, you can use CHECK TABLE and RE-PAIR TABLE to check and repair MyISAM tables. This option previously was named --skip-locking.

- `--skip-grant-tables`

  This option causes the server not to use the privilege system at all. This gives everyone *full access* to all databases! (You can tell a running server to start using the grant tables again by executing a mysqladmin flush-privileges or mysqladmin reload command, or by issuing a FLUSH PRIVILEGES statement.)

- `--skip-host-cache`

  Do not use the internal hostname cache for faster name-to-IP resolution. Instead, query the DNS

server every time a client connects. See Section 7.5.6, "How MySQL Uses DNS".

- `--skip-innodb`

  Disable the `InnoDB` storage engine. This saves memory and disk space and might speed up some operations. Do not use this option if you require `InnoDB` tables.

- `--skip-isam`

  Disable the `ISAM` storage engine. As of MySQL 4.1, `ISAM` is disabled by default, so this option applies only if the server was configured with support for `ISAM`. This option was added in MySQL 4.1.1.

- `--skip-name-resolve`

  Do not resolve hostnames when checking client connections. Use only IP numbers. If you use this option, all `Host` column values in the grant tables must be IP numbers or `localhost`. See Section 7.5.6, "How MySQL Uses DNS".

- `--skip-ndbcluster`

  Disable the `NDB Cluster` storage engine. This is the default for binaries that were built with `NDB Cluster` storage engine support, this means that the system only allocates memory and other resources for this storage engine if it is explicitly enabled.

- `--skip-networking`

  Don't listen for TCP/IP connections at all. All interaction with `mysqld` must be made via named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are allowed. See Section 7.5.6, "How MySQL Uses DNS".

- `--skip-new`

  Don't use new, possibly wrong routines.

- `--skip-symlink`

  This is the old form of `--skip-symbolic-links`, for use before MySQL 4.0.13.

- `--standalone`

  Windows-NT based systems only, instructs MySQL server to not run as a service.

- `--symbolic-links`, `--skip-symbolic-links`

  Enable or disable symbolic link support. This option has different effects on Windows and Unix:

  - On Windows, enabling symbolic links allows you to establish a symbolic link to a database directory by creating a `directory.sym` file that contains the path to the real directory. See Section 7.6.1.3, "Using Symbolic Links for Databases on Windows".

  - On Unix, enabling symbolic links means that you can link a `MyISAM` index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` options of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See Section 13.1.5, "`CREATE TABLE` Syntax".

  This option was added in MySQL 4.0.13.

- `--skip-safemalloc`

  If MySQL is configured with `--with-debug=full`, all MySQL programs check for memory overruns during each memory allocation and memory freeing operation. This checking is very

slow, so for the server you can avoid it when you don't need it by using the `--skip-safemalloc` option.

- `--skip-show-database`

With this option, the `SHOW DATABASES` statement is allowed only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. Without this option, `SHOW DATABASES` is allowed to all users, but displays each database name only if the user has the `SHOW DATABASES` privilege or some privilege for the database.

- `--skip-stack-trace`

Don't write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See Section F.1, "Debugging a MySQL Server".

- `--skip-thread-priority`

Disable using thread priorities for faster response time.

- `--socket=path`

On Unix, this option specifies the Unix socket file to use for local connections. The default value is `/tmp/mysql.sock`. On Windows, the option specifies the pipe name to use for local connections that use a named pipe. The default value is `MySQL`.

- `--sql-mode=value[,value[,value...]]`

Set the SQL mode for MySQL. See Section 5.3.2, "The Server SQL Mode". This option was added in 3.23.41.

- `--temp-pool`

This option causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating many new files with different names. With the old behavior, Linux seems to "leak" memory, because it's being allocated to the directory entry cache rather than to the disk cache.

- `--transaction-isolation=level`

Sets the default transaction isolation level, which can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See Section 13.4.6, "SET TRANSACTION Syntax".

- `--tmpdir=path`, `-t path`

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. Starting from MySQL 4.1, this option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters ('`:`') on Unix and semicolon characters ('`;`') on Windows, NetWare, and OS/2. If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based filesystem or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- `--user={user_name | user_id}`, `-u {user_name | user_id}`

Run the `mysqld` server as the user having the name *user_name* or the numeric user ID *user_id*. ("User" in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See Sec-

tion 5.5.1, "General Security Guidelines".

Starting from MySQL 3.23.56 and 4.0.12: To avoid a possible security hole where a user adds a `--user=root` option to some `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--version, -V`

  Display version information and exit.

As of MySQL 4.0, you can assign a value to a server system variable by using an option of the form `--var_name=value`. For example, `--key_buffer_size=32M` sets the `key_buffer_size` variable to a value of 32MB.

Note that when setting a variable to a value, MySQL might automatically correct it to stay within a given range, or adjust the value to the closest allowable value if only certain values are allowed.

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. However, this syntax is deprecated as of MySQL 4.0.

You can find a full description for all variables in Section 5.3.3, "Server System Variables". The section on tuning server parameters includes information on how to optimize them. See Section 7.5.2, "Tuning Server Parameters".

You can change the values of most system variables for a running server with the `SET` statement. See Section 13.5.3, "`SET` Syntax".

If you want to restrict the maximum value that a startup option can be set to with `SET`, you can define this by using the `--maximum-var_name` command-line option.

5.3.2. The Server SQL Mode

The MySQL server can operate in different SQL modes, and (as of MySQL 4.1) can apply these modes differentially for different clients. This allows an application to tailor server operation to its own requirements.

Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="modes"` option. The value also can be empty (`--sql-mode=""`) if you want to reset it.

Beginning with MySQL 4.1, you can also change the SQL mode after startup time by setting the `sql_mode` variable with a `SET [SESSION|GLOBAL] sql_mode='modes'` statement. Setting the `GLOBAL` variable requires the `SUPER` privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Any client can change its session `sql_mode` value.

`modes` is a list of different modes separated by comma ('`,`') characters. You can retrieve the current mode by issuing a `SELECT @@sql_mode` statement. The default value is empty (no modes set).

The most important `sql_mode` values are probably these:

-

ANSI

Change syntax and behavior to be more conformant to standard SQL. (New in MySQL 4.1.1)

- STRICT_TRANS_TABLES

If a value could not be inserted as given into a transactional table, abort the statement. For a non-transactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More detail is given later in this section. (New in MySQL 5.0.2)

- TRADITIONAL

Make MySQL behave like a "traditional" SQL database system. A simple description of this mode is "give an error instead of a warning" when inserting an incorrect value into a column. **Note**: The INSERT/UPDATE aborts as soon as the error is noticed. This may not be what you want if you are using a non-transactional storage engine, because data changes made prior to the error are not be rolled back, resulting in a "partially done" update. (New in MySQL 5.0.2)

When this manual refers to "strict mode," it means a mode where at least one of STRICT_TRANS_TABLES or STRICT_ALL_TABLES is enabled.

The following list describes all the supported modes:

- ALLOW_INVALID_DATES

Don't do full checking of dates in strict mode. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This is very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation). This mode applies to DATE and DATETIME columns. It does not apply TIMESTAMP columns, which always require a valid date.

This mode is new in MySQL 5.0.2. Before 5.0.2, this was the default MySQL date-handling mode. As of 5.0.2, enabling strict mode causes the server to require that month and day values be legal, not just in the range from 1 to 12 and 1 to 31. For example, '2004-04-31' is legal with strict mode disabled, but illegal with strict mode enabled. To allow such dates in strict mode, enable ALLOW_INVALID_DATES as well.

- ANSI_QUOTES

Treat '"' as an identifier quote character (like the '`' quote character) and not as a string quote character. You can still use '`' to quote identifiers in ANSI mode. With ANSI_QUOTES enabled, you cannot use double quotes to quote a literal string, because it is interpreted as an identifier. (New in MySQL 4.0.0)

- ERROR_FOR_DIVISION_BY_ZERO

Produce an error in strict mode (otherwise a warning) when we encounter a division by zero (or MOD(X,0)) during an INSERT or UPDATE, or in any expression (for example, in a select list or WHERE clause) that involves table data and a division by zero. If this mode is not given, MySQL instead returns NULL for divisions by zero. If used in INSERT IGNORE or UPDATE IGNORE, MySQL generates a warning for divisions by zero, but the result of the operation is NULL. (New in MySQL 5.0.2)

- HIGH_NOT_PRECEDENCE

From MySQL 5.0.2 on, the NOT operator precedence is handled so that expressions such as NOT a BETWEEN b AND c are parsed as NOT (a BETWEEN b AND c). Before MySQL 5.0.2, the expression is parsed as (NOT a) BETWEEN b AND c. The old higher-precedence behavior can be obtained by enabling the HIGH_NOT_PRECEDENCE SQL mode. (New in MySQL 5.0.2)

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
        -> 0
mysql> SET sql_mode = 'broken_not';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
        -> 1
```

-
  IGNORE_SPACE

  Allow spaces between a function name and the '(' character. This forces all function names to be treated as reserved words. As a result, if you want to access any database, table, or column name that is a reserved word, you must quote it. For example, because there is a USER() function, the name of the user table in the mysql database and the User column in that table become reserved, so you must quote them:

  ```
  SELECT "User" FROM mysql."user";
  ```

  (New in MySQL 4.0.0)

-
  NO_AUTO_CREATE_USER

  Prevent GRANT from automatically creating new users if it would otherwise do so, unless a password also is specified. (New in MySQL 5.0.2)

-
  NO_AUTO_VALUE_ON_ZERO

  NO_AUTO_VALUE_ON_ZERO affects handling of AUTO_INCREMENT columns. Normally, you generate the next sequence number for the column by inserting either NULL or 0 into it. NO_AUTO_VALUE_ON_ZERO suppresses this behavior for 0 so that only NULL generates the next sequence number. (New in MySQL 4.1.1)

  This mode can be useful if 0 has been stored in a table's AUTO_INCREMENT column. (This is not a recommended practice, by the way.) For example, if you dump the table with mysqldump and then reload it, MySQL normally generates new sequence numbers when it encounters the 0 values, resulting in a table with different contents than the one that was dumped. Enabling NO_AUTO_VALUE_ON_ZERO before reloading the dump file solves this problem. As of MySQL 4.1.1, mysqldump automatically includes a statement in the dump output to enable NO_AUTO_VALUE_ON_ZERO.

-
  NO_BACKSLASH_ESCAPES

  Disable the use of the backslash character ('\') as an escape character within strings. With this mode enabled, backslash becomes any ordinary character like any other. (New in MySQL 5.0.1)

-
  NO_DIR_IN_CREATE

  When creating a table, ignore all INDEX DIRECTORY and DATA DIRECTORY directives. This option is useful on slave replication servers. (New in MySQL 4.0.15)

- NO_ENGINE_SUBSTITUTION

Prevents automatic substitution of storage engine when the requested storage engine is disabled or not compiled in.

- NO_FIELD_OPTIONS

  Don't print MySQL-specific column options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode. (New in MySQL 4.1.1)

- NO_KEY_OPTIONS

  Don't print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode. (New in MySQL 4.1.1)

- NO_TABLE_OPTIONS

  Don't print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode. (New in MySQL 4.1.1)

- NO_UNSIGNED_SUBTRACTION

  In subtraction operations, don't mark the result as `UNSIGNED` if one of the operands is unsigned. Note that this makes `UNSIGNED BIGINT` not 100% usable in all contexts. See Section 12.8, "Cast Functions and Operators". (New in MySQL 4.0.2)

- NO_ZERO_DATE

  In strict mode, don't allow `'0000-00-00'` as a valid date. You can still insert zero dates with the `IGNORE` option. When not in strict mode, the date is accepted but a warning is generated. (New in MySQL 5.0.2)

- NO_ZERO_IN_DATE

  In strict mode, don't accept dates where the month or day part is 0. If used with the `IGNORE` option, we insert a `'0000-00-00'` date for any such date. When not in strict mode, the date is accepted but a warning is generated. (New in MySQL 5.0.2)

- ONLY_FULL_GROUP_BY

  Don't allow queries that in the `GROUP BY` part refer to a not selected column. (New in MySQL 4.0.0)

- PIPES_AS_CONCAT

  Treat `||` as a string concatenation operator (same as `CONCAT()`) rather than as a synonym for `OR`. (New in MySQL 4.0.0)

- REAL_AS_FLOAT

  Treat `REAL` as a synonym for `FLOAT` rather than as a synonym for `DOUBLE`. (New in MySQL 4.0.0)

- STRICT_ALL_TABLES

  Enable strict mode for all storage engines. Invalid data values are rejected. Additional detail fol-

lows. (New in MySQL 5.0.2)

-
  STRICT_TRANS_TABLES

  Enable strict mode for transactional storage engines, and when possible for non-transactional storage engines. Additional detail follows. (New in MySQL 5.0.2)

Strict mode controls how MySQL handles input values that are invalid or missing. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a column that has no explicit DEFAULT clause in its definition.

For transactional tables, an error occurs for invalid or missing values in a statement when either of the STRICT_ALL_TABLES or STRICT_TRANS_TABLES modes are enabled. The statement is aborted and rolled back.

For non-transactional tables, the behavior is the same for either mode, if the bad value occurs in the first row to be inserted or updated. The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict option is enabled:

- For STRICT_ALL_TABLES, MySQL returns an error and ignores the rest of the rows. However, in this case, the earlier rows still have been inserted or updated. This means that you might get a partial update, which might not be what you want. To avoid this, it's best to use single-row statements because these can be aborted without changing the table.

- For STRICT_TRANS_TABLES, MySQL converts an invalid value to the closest valid value for the column and insert the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in Section 13.1.5, "CREATE TABLE Syntax".

Strict mode disallows invalid date values such as '2004-04-31'. It does not disallow dates with zero parts such as 2004-04-00' or "zero" dates. To disallow these as well, enable the NO_ZERO_IN_DATE and NO_ZERO_DATE SQL modes in addition to strict mode.

If you are not using strict mode (that is, neither STRICT_TRANS_TABLES nor STRICT_ALL_TABLES is enabled), MySQL inserts adjusted values for invalid or missing values and produces warnings. In strict mode, you can produce this behavior by using INSERT IGNORE or UPDATE IGNORE. See Section 13.5.4.22, "SHOW WARNINGS Syntax".

The following special modes are provided as shorthand for combinations of mode values from the preceding list. All are available as of MySQL 4.1.1, except TRADITIONAL (5.0.2).

The descriptions include all mode values that are available in the most recent version of MySQL. For older versions, a combination mode does not include individual mode values that are not available except in newer versions.

-
  ANSI

  Equivalent to REAL_AS_FLOAT, PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE. Before MySQL 4.1.11 and 5.0.3, ANSI also includes ONLY_FULL_GROUP_BY. See Section 1.8.3, "Running MySQL in ANSI Mode".

-
  DB2

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `MAXDB`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `MSSQL`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `MYSQL323`

  Equivalent to `NO_FIELD_OPTIONS`, `HIGH_NOT_PRECEDENCE`.

- `MYSQL40`

  Equivalent to `NO_FIELD_OPTIONS`, `HIGH_NOT_PRECEDENCE`.

- `ORACLE`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `POSTGRESQL`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `TRADITIONAL`

  Equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`.

5.3.3. Server System Variables

The server maintains many system variables that indicate how it is configured. All of them have default values. They can be set at server startup using options on the command line or in option files. Most of them can be set at runtime using the `SET` statement.

Beginning with MySQL 4.0.3, the `mysqld` server maintains two kinds of variables. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections.

When the server starts, it initializes all global variables to their default values. These defaults can be changed by options specified in option files or on the command line. After the server starts, those global variables that are dynamic can be changed by connecting to the server and issuing a `SET GLOBAL` *var_name* statement. To change a global variable, you must have the `SUPER` privilege.

The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For those session variables that are dynamic, the client can change them by issuing a `SET SESSION` *var_name* statement. Setting a session variable requires no special privilege, but a cli-

ent can change only its own session variables, not those of any other client.

A change to a global variable is visible to any client that accesses that global variable. However, it affects the corresponding session variable that is initialized from the global variable only for clients that connect after the change. It does not affect the session variable for any client that is currently connected (not even that of the client that issues the SET GLOBAL statement).

When setting a variable using a startup option, variable values can be given with a suffix of K, M, or G to indicate kilobytes, megabytes, or gigabytes, respectively. For example, the following command starts the server with a key buffer size of 16 megabytes:

```
mysqld --key_buffer_size=16M
```

Before MySQL 4.0, use this syntax instead:

```
mysqld --set-variable=key_buffer_size=16M
```

The lettercase of suffix letters does not matter; 16M and 16m are equivalent.

At runtime, use the SET statement to set system variables. In this context, suffix letters cannot be used, but the value can take the form of an expression:

```
mysql> SET sort_buffer_size = 10 * 1024 * 1024;
```

To specify explicitly whether to set the global or session variable, use the GLOBAL or SESSION options:

```
mysql> SET GLOBAL sort_buffer_size = 10 * 1024 * 1024;
mysql> SET SESSION sort_buffer_size = 10 * 1024 * 1024;
```

Without either option, the statement sets the session variable.

The variables that can be set at runtime are listed in Section 5.3.3.1, "Dynamic System Variables".

If you want to restrict the maximum value to which a system variable can be set with the SET statement, you can specify this maximum by using an option of the form --maximum-*var_name* at server startup. For example, to prevent the value of query_cache_size from being increased to more than 32MB at runtime, use the option --maximum-query_cache_size=32M. This feature is available as of MySQL 4.0.2.

You can view system variables and their values by using the SHOW VARIABLES statement. See Section 9.4, "System Variables" for more information.

```
mysql> SHOW VARIABLES;
+-------------------------------+----------------------------------------

```

Most system variables are described here. Variables with no version indicated have been present since at least MySQL 3.22. InnoDB system variables are listed at Section 15.5, "InnoDB Startup Options".

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Information on tuning these variables can be found in Section 7.5.2, "Tuning Server Parameters".

- auto_increment_increment

   auto_increment_increment and auto_increment_offset are intended for use with master-to-master replication, and can be used to control the operation of AUTO_INCREMENT columns. Both variables can be set globally or locally, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 will cause its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 will cause its value to be set to 65,535 instead. Attempting to set the value of auto_increment_increment or of auto_increment_offset to a non-integer value gives rise to an error, and the actual value of the variable remains unchanged in such a case.

   These two variables effect AUTO_INCREMENT column behaviour as follows:

   - auto_increment_increment controls the interval by which the column value is incremented. For example:

      ```
      mysql> SHOW VARIABLES LIKE 'auto_inc%';
      +--------------------------+-------+
      | Variable_name            | Value |
      +--------------------------+-------+
      ```

```
| auto_increment_increment | 1     |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1 (col INT NOT NULL AUTO_INCREMENT PRIMARY KE
Query OK, 0 rows affected (0.04 sec)

mysql> SET @auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)
```

(Note how SHOW VARIABLES is used here to obtain the current values for these variables.)

• auto_increment_offset determines the starting point for the AUTO_INCREMENT
  column value. Consider the following, assuming that these commands are executed during
  the same session as the previous example:

```
mysql> SET @auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2 (col INT NOT NULL AUTO_INCREMENT PRIMARY KE
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
|   5 |
|  15 |
```

```
|    25 |
|    35 |
+-----+
4 rows in set (0.02 sec)
```

> If the value of auto_increment_offset is greater than that of auto_increment_increment, then the value of auto_increment_offset is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an AUTO_INCREMENT column, the results may seem counterintuitive, as the series of AUTO_INCREMENT values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the AUTO_INCREMENT column. In other words, the series is calculated like so:

auto_increment_offset + *N* * auto_increment_increment

where *N* is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
|  35 |
|  45 |
|  55 |
|  65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for auto_increment_increment and auto_increment_offset generate the series 5 + *N* * 10, that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the col column prior to the INSERT is 31, and the next available value in the AUTO_INCREMENT

series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is important to remember that it is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behaviour of all `AUTO_INCREMENT` columns in **all** tables on the MySQL server. If one of these variables is set globally, then its effects persist until the global value is changed or overridden by setting them locally, or until `mysqld` is restarted; if set locally, then the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The `auto_increment_increment` variable was added in MySQL 5.0.2. Its default value is 1. See Chapter 6, *Replication in MySQL.*

- `auto_increment_offset`

  This variable was introduced in MySQL 5.0.2. Its default value is 1. For particulars, see the description for `auto_increment_increment`.

- `ansi_mode`

  This is `ON` if `mysqld` was started with `--ansi`. See Section 1.8.3, "Running MySQL in ANSI Mode". This variable was added in MySQL 3.23.6 and removed in 3.23.41. See the description for `sql_mode`.

- `back_log`

  The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

  In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. Attempting to set `back_log` higher than your operating system limit is ineffective.

- `basedir`

  The MySQL installation base directory. This variable can be set with the `--basedir` option.

- `bdb_cache_size`

  The size of the buffer that is allocated for caching indexes and rows for `BDB` tables. If you don't use `BDB` tables, you should start `mysqld` with `--skip-bdb` to not waste memory for this cache. This variable was added in MySQL 3.23.14.

- `bdb_home`

  The base directory for `BDB` tables. This should be assigned the same value as the `datadir` variable. This variable was added in MySQL 3.23.14.

- `bdb_log_buffer_size`

  The size of the buffer that is allocated for caching indexes and rows for `BDB` tables. If you don't use `BDB` tables, you should set this to 0 or start `mysqld` with `--skip-bdb` to not waste memory for this cache. This variable was added in MySQL 3.23.31.

- `bdb_logdir`

The directory where the BDB storage engine writes its log files. This variable can be set with the `--bdb-logdir` option. This variable was added in MySQL 3.23.14.

- `bdb_max_lock`

The maximum number of locks you can have active on a BDB table (10,000 by default). You should increase this if errors such as the following occur when you perform long transactions or when `mysqld` has to examine many rows to calculate a query:

```
bdb: Lock table is out of available locks
Got error 12 from ...
```

This variable was added in MySQL 3.23.29.

- `bdb_shared_data`

This is `ON` if you are using `--bdb-shared-data`. This variable was added in MySQL 3.23.29.

- `bdb_tmpdir`

The value of the `--bdb-tmpdir` option. This variable was added in MySQL 3.23.14.

- `bdb_version`

See the description for `version_bdb`.

- `binlog_cache_size`

The size of the cache to hold the SQL statements for the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and, starting from MySQL 4.1.2, if the server has binary log enabled (`--log-bin` option). If you often use big, multiple-statement transactions, you can increase this to get more performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. This variable was added in MySQL 3.23.29. See Section 5.10.4, "The Binary Log".

- `bulk_insert_buffer_size`

`MyISAM` uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA INFILE`. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. **Note**: This cache is used only when adding data to a non-empty table. The default value is 8MB. This variable was added in MySQL 4.0.3. This variable previously was named `myisam_bulk_insert_tree_size`.

- `character_set`

The default character set. This variable was added in MySQL 3.23.3, then removed in MySQL 4.1.1 and replaced by the various `character_set_xxx` variables.

- `character_set_client`

The character set for statements that arrive from the client. This variable was added in MySQL 4.1.1.

- `character_set_connection`

The character set used for literals that do not have a character set introducer and for number-to-string conversion. This variable was added in MySQL 4.1.1.

- `character_set_database`

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`. This variable was added in MySQL 4.1.1.

- `character_set_results`

The character set used for returning query results to the client. This variable was added in MySQL 4.1.1.

- `character_set_server`

The server default character set. This variable was added in MySQL 4.1.1.

- `character_set_system`

The character set used by the server for storing identifiers. The value is always `utf8`. This variable was added in MySQL 4.1.1.

- `character_sets`

The supported character sets. This variable was added in MySQL 3.23.15 and removed in MySQL 4.1.1. (Use `SHOW CHARACTER SET` for a list of character sets.)

- `character_sets_dir`

The directory where character sets are installed. This variable was added in MySQL 4.1.2.

- `collation_connection`

The collation of the connection character set. This variable was added in MySQL 4.1.1.

- `collation_database`

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`. This variable was added in MySQL 4.1.1.

- `collation_server`

The server default collation. This variable was added in MySQL 4.1.1.

- `completion_type`

The transaction completion type:

- If the value is 0 (the default), `COMMIT` and `ROLLBACK` are unaffected.

- If the value is 1, `COMMIT` and `ROLLBACK` are equivalent to `COMMIT AND CHAIN` and `ROLLBACK AND CHAIN`, respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)

- If the value is 2, `COMMIT` and `ROLLBACK` are equivalent to `COMMIT RELEASE` and `ROLLBACK RELEASE`, respectively. (The server disconnects after terminating the transaction.)

This variable was added in MySQL 5.0.3

- `concurrent_insert`

If `ON` (the default), MySQL allows `INSERT` and `SELECT` statements to run concurrently for `MyISAM` tables that have no free blocks in the middle. You can turn this option off by starting `mysqld` with `--safe` or `--skip-new`. This variable was added in MySQL 3.23.7.

In MySQL 5.0.6 this variable was changed to an integer that takes 3 values:

Value	Description
0	Off
1	(Default) Enables concurrent insert for MyISAM tables that doesn't have holes
2	Enables concurrent inserts for all MyISAM tables. If table has a hole and is in use by another thread the new row will be inserted at end of table. If table is not in use then MySQL will do a normal read lock and insert the new row into the hole.

- connect_timeout

  The number of seconds the mysqld server waits for a connect packet before responding with Bad handshake.

- convert_character_set

  The current character set mapping that was set by SET CHARACTER SET. This variable was removed in MySQL 4.1.

- datadir

  The MySQL data directory. This variable can be set with the --datadir option.

- date_format

  This variable is not implemented.

- datetime_format

  This variable is not implemented.

- default_week_format

  The default mode value to use for the WEEK() function. This variable is available as of MySQL 4.0.14.

- delay_key_write

  This option applies only to MyISAM tables. It can have one of the following values to affect handling of the DELAY_KEY_WRITE table option that can be used in CREATE TABLE statements.

Option	Description
OFF	DELAY_KEY_WRITE is ignored.
ON	MySQL honors the DELAY_KEY_WRITE option for CREATE TABLE. This is the default value.
ALL	All new opened tables are treated as if they were created with the DELAY_KEY_WRITE option enabled.

If DELAY_KEY_WRITE is enabled, this means that the key buffer for tables with this option are not flushed on every index update, but only when a table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all MyISAM tables by starting the server with the --myisam-recover option (for example, --myisam-recover=BACKUP,FORCE). See Section 5.3.1, "mysqld Command-Line Options" and Section 14.1.1, "MyISAM Startup Options".

Note that `--external-locking` doesn't offer any protection against index corruption for tables that use delayed key writes.

This variable was added in MySQL 3.23.8.

- `delayed_insert_limit`

  After inserting `delayed_insert_limit` delayed rows, the `INSERT DELAYED` handler thread checks whether there are any `SELECT` statements pending. If so, it allows them to execute before continuing to insert delayed rows.

- `delayed_insert_timeout`

  How long an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

- `delayed_queue_size`

  This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

- `div_precision_increment`

  This variable indicates the number of digits of precision by which to increase the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+--------+
| 1/7    |
+--------+
| 0.1429 |
+--------+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+----------------+
| 1/7            |
+----------------+
| 0.142857142857 |
+----------------+
```

  This variable was added in MySQL 5.0.6.

- `engine_condition_pushdown`

  This variable applies to NDB. By default it is 0 (`OFF`): If you execute a query such as `SELECT * FROM t WHERE mycol = 42`, where `mycol` is an unindexed column, the query is executed as a full table scan on every NDB node. Each node sends every row to the MySQL server, which applies the `WHERE` condition. If `engine_condition_pushdown` is set to 1 (`ON`), the condition is "pushed down" to the storage engine and sent to the NDB nodes. Each node performs the scan, and only sends back to the MySQL server the rows that match the condition.

  This variable was added in MySQL 5.0.3. Before that, the default NDB behavior is the same as for a value of `OFF`.

- `expire_logs_days`

  The number of days for automatic binary log removal. The default is 0, which means "no automatic removal". Possible removals happen at startup and at binary log rotation. This variable was added in MySQL 4.1.0.

- `flush`

  This is `ON` if you have started `mysqld` with the `--flush` option. This variable was added in MySQL 3.22.9.

- `flush_time`

  If this is set to a non-zero value, all tables are closed every `flush_time` seconds to free up resources and sync unflushed data to disk. We recommend this option only on Windows 9x or Me, or on systems with minimal resources available. This variable was added in MySQL 3.22.18.

- `ft_boolean_syntax`

  The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. This variable was added in MySQL 4.0.1. See Section 12.7.1, "Boolean Full-Text Searches".

  The default variable value is `'+ -><()~*:""&|'`. The rules for changing the value are as follows:

  - Operator function is determined by position within the string.

  - The replacement value must be 14 characters.

  - Each character must be an ASCII non-alphanumeric character.

  - Either the first or second character must be a space.

  - No duplicates are allowed except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.

  - Positions 10, 13, and 14 (which by default are set to ':', '&', and '|') are reserved for future extensions.

- `ft_max_word_len`

  The maximum length of the word to be included in a `FULLTEXT` index. This variable was added in MySQL 4.0.0.

  Note: `FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE` *tbl_name* `QUICK`.

- `ft_min_word_len`

  The minimum length of the word to be included in a `FULLTEXT` index. This variable was added in MySQL 4.0.0.

  Note: `FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE` *tbl_name* `QUICK`.

- `ft_query_expansion_limit`

  The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`. This variable was added in MySQL 4.1.1.

- `ft_stopword_file`

  The file from which to read the list of stopwords for full-text searches. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `myisam/ft_static.c` file). Setting this variable to the empty string (`''`) disables stopword filtering. This variable was added in MySQL 4.0.10.

  Note: `FULLTEXT` indexes must be rebuilt after changing this variable or the contents of the stopword file. Use `REPAIR TABLE` *tbl_name* `QUICK`.

- `group_concat_max_len`

  The maximum allowed result length for the `GROUP_CONCAT()` function. This variable was added in MySQL 4.1.0.

- `have_archive`

  `YES` if `mysqld` supports `ARCHIVE` tables, `NO` if not. This variable was added in MySQL 4.1.3.

- `have_bdb`

  `YES` if `mysqld` supports `BDB` tables. `DISABLED` if `--skip-bdb` is used. This variable was added in MySQL 3.23.30.

- `have_blackhole_engine`

  `YES` if `mysqld` supports `BLACKHOLE` tables, `NO` if not. This variable was added in MySQL 4.1.11.

- `have_compress`

  Whether the `zlib` compression library is available to the server. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used. This variable was added in MySQL 4.1.1.

- `have_crypt`

  Whether the `crypt()` system call is available to the server. If not, the `CRYPT()` function cannot be used. This variable was added in MySQL 4.0.10.

- `have_csv`

  `YES` if `mysqld` supports `ARCHIVE` tables, `NO` if not. This variable was added in MySQL 4.1.4.

- `have_example_engine`

  `YES` if `mysqld` supports `EXAMPLE` tables, `NO` if not. This variable was added in MySQL 4.1.4.

- `have_federated_engine`

  `YES` if `mysqld` supports `FEDERATED` tables, `NO` if not. This variable was added in MySQL 5.0.3.

- `have_geometry`

  Whether the server supports spatial data types. This variable was added in MySQL 4.1.3.

- `have_innodb`

  `YES` if `mysqld` supports `InnoDB` tables. `DISABLED` if `--skip-innodb` is used. This variable was added in MySQL 3.23.37.

- `have_isam`

  `YES` if `mysqld` supports `ISAM` tables. `DISABLED` if `--skip-isam` is used. This variable was added in MySQL 3.23.30.

- `have_ndbcluster`

  `YES` if `mysqld` supports `NDB Cluster` tables. `DISABLED` if `--skip-ndbcluster` is used. This variable was added in MySQL 4.1.2.

- `have_openssl`

  `YES` if `mysqld` supports SSL (encryption) of the client/server protocol. This variable was ad-

ded in MySQL 3.23.43.

- `have_query_cache`

  `YES` if `mysqld` supports the query cache. This variable was added in MySQL 4.0.2.

- `have_raid`

  `YES` if `mysqld` supports the `RAID` option. This variable was added in MySQL 3.23.30.

- `have_rtree_keys`

  Whether `RTREE` indexes are available. (These are used for spatial indexed in `MyISAM` tables.) This variable was added in MySQL 4.1.3.

- `have_symlink`

  Whether symbolic link support is enabled. This is required on Unix for support of the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.

  This variable was added in MySQL 4.0.0.

- `init_connect`

  A string to be executed by the server for each client that connects. The string consists of one or more SQL statements. To specify multiple statements, separate them by semicolon characters. For example, each client begins by default with autocommit mode enabled. There is no global server variable to specify that autocommit should be disabled by default, but `init_connect` can be used to achieve the same effect:

  ```
  SET GLOBAL init_connect='SET AUTOCOMMIT=0';
  ```

  This variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

  ```
  [mysqld]
  init_connect='SET AUTOCOMMIT=0'
  ```

  Note that the content of `init_connect` is not executed for users having the `SUPER` privilege; this is in case that content has been wrongly set (contains a wrong query, for example with a syntax error), thus making all connections fail. Not executing it for `SUPER` users enables those to open a connection and fix `init_connect`. This variable was added in MySQL 4.1.2.

- `init_file`

  The name of the file specified with the `--init-file` option when you start the server. This is a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments. This variable was added in MySQL 3.23.2.

- `init_slave`

  This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable. This variable was added in MySQL 4.1.2.

- `innodb_`*`xxx`*

  The `InnoDB` system variables are listed at Section 15.5, "`InnoDB` Startup Options".

- `interactive_timeout`

  The number of seconds the server waits for activity on an interactive connection before closing

it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- `join_buffer_size`

  The size of the buffer that is used for full joins (joins that do not use indexes). Normally the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

-

  `key_buffer_size`

  Index blocks for `MyISAM` and `ISAM` tables are buffered and are shared by all threads. `key_buffer_size` is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

  The maximum allowable setting for `key_buffer_size` is 4GB. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform.

  Increase the value to get better index handling (for all reads and multiple writes) to as much as you can afford. Using a value that is 25% of total memory on a machine that mainly runs MySQL is quite common. However, if you make the value too large (for example, more than 50% of your total memory) your system might start to page and become extremely slow. MySQL relies on the operating system to perform filesystem caching for data reads, so you must leave some room for the filesystem cache.

  For even more speed when writing many rows at the same time, use `LOCK TABLES`. See Section 13.4.5, "`LOCK TABLES` and `UNLOCK TABLES` Syntax".

  You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests`, `Key_reads`, `Key_write_requests`, and `Key_writes` status variables. See Section 13.5.4, "`SHOW` Syntax".

  The `Key_reads`/`Key_read_requests` ratio should normally be less than 0.01. The `Key_writes`/`Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

  The fraction of the key buffer in use can be determined using `key_buffer_size` in conjunction with the `Key_blocks_unused` status variable and the buffer block size. From MySQL 4.1.1 on, the buffer block size is available from the `key_cache_block_size` server variable. The fraction of the buffer in use is:

  `1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)`

  This value is an approximation because some space in the key buffer may be allocated internally for administrative structures.

  Before MySQL 4.1.1, key cache blocks are 1024 bytes, and before MySQL 4.1.2, `Key_blocks_unused` is unavailable. The `Key_blocks_used` variable can be used as follows to determine the fraction of the key buffer in use:

  `(Key_blocks_used * 1024) / key_buffer_size`

  However, `Key_blocks_used` indicates the maximum number of blocks that have ever been in use at once, so this formula does not necessary represent the current fraction of the buffer that is in use.

As of MySQL 4.1, it is possible to create multiple MyISAM key caches. The size limit of 4GB applies to each cache individually, not as a group. See Section 7.4.6, "The `MyISAM` Key Cache".

- `key_cache_age_threshold`

  This value controls the demotion of buffers from the hot sub-chain of a key cache to the warm sub-chain. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. This variable was added in MySQL 4.1.1. See Section 7.4.6, "The `My-ISAM` Key Cache".

- `key_cache_block_size`

  The size in bytes of blocks in the key cache. The default value is 1024. This variable was added in MySQL 4.1.1. See Section 7.4.6, "The `MyISAM` Key Cache".

- `key_cache_division_limit`

  The division point between the hot and warm sub-chains of the key cache buffer chain. The value is the percentage of the buffer chain to use for the warm sub-chain. Allowable values range from 1 to 100. The default value is 100. This variable was added in MySQL 4.1.1. See Section 7.4.6, "The `MyISAM` Key Cache".

- `language`

  The language used for error messages.

- `large_file_support`

  Whether `mysqld` was compiled with options for large file support. This variable was added in MySQL 3.23.28.

- `large_pages`

  Indicates whether large page support is enabled. This variable was added in MySQL 5.0.3.

- `license`

  The type of license the server has. This variable was added in MySQL 4.0.19.

- `local_infile`

  Whether `LOCAL` is supported for `LOAD DATA INFILE` statements. This variable was added in MySQL 4.0.3.

- `locked_in_memory`

  Whether `mysqld` was locked in memory with `--memlock`. This variable was added in MySQL 3.23.25.

- `log`

  Whether logging of all queries to the general query log is enabled. See Section 5.10.2, "The General Query Log".

- `log_bin`

  Whether the binary log is enabled. This variable was added in MySQL 3.23.14. See Section 5.10.4, "The Binary Log".

- log_bin_trust_routine_creators

  This variable applies when binary logging is enabled. It controls whether stored routine creators

can be trusted not to create stored routines that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not allowed to create or alter stored routines unless they have the SUPER privilege in addition to the CREATE ROUTINE or ALTER ROUTINE privilege.

A setting of 0 also enforces the restriction that a routine must be declared with the DETERMINISTIC characteristic, or with the READS SQL DATA or NO SQL characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored routine creation.

See Section 18.4, "Binary Logging of Stored Routines and Triggers".

This variable was added in MySQL 5.0.6.

- `log_error`

The location of the error log. This variable was added in MySQL 4.0.10.

- `log_slave_updates`

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this to have any effect. This variable was added in MySQL 3.23.17. See Section 6.8, "Replication Startup Options".

- `log_slow_queries`

Whether slow queries should be logged. "Slow" is determined by the value of the `long_query_time` variable. This variable was added in MySQL 4.0.2. See Section 5.10.5, "The Slow Query Log".

- `log_update`

Whether the update log is enabled. This variable was added in MySQL 3.22.18. Note that the binary log is preferable to the update log, which is unavailable as of MySQL 5.0. See Section 5.10.3, "The Update Log".

- `log_warnings`

Whether to produce additional warning messages. This variable was added in MySQL 4.0.3. It is enabled by default as of MySQL 4.0.19 and 4.1.2. As of MySQL 4.0.21 and 4.1.3, aborted connections are not logged to the error log unless the value is greater than 1.

- `long_query_time`

If a query takes longer than this many seconds, the `Slow_queries` status variable is incremented. If you are using the `--log-slow-queries` option, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. See Section 5.10.5, "The Slow Query Log".

- `low_priority_updates`

If set to 1, all INSERT, UPDATE, DELETE, and LOCK TABLE WRITE statements wait until there is no pending SELECT or LOCK TABLE READ on the affected table. This variable previously was named `sql_low_priority_updates`. It was added in MySQL 3.22.5.

- `lower_case_file_system`

This variable indicates whether the filesystem where the data directory is located has case insensitive filenames. ON means filenames are case insensitive, OFF means they are case sensitive. This variable was added in MySQL 4.0.19.

- `lower_case_table_names`

If set to 1, table names are stored in lowercase on disk and table name comparisons are not case sensitive. This variable was added in MySQL 3.23.6. If set to 2 (new in 4.0.18), table names are stored as given but compared in lowercase. From MySQL 4.0.2, this option also applies to database names. From 4.1.1, it also applies to table aliases. See Section 9.2.2, "Identifier Case Sensitivity".

If you are using `InnoDB` tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

You should *not* set this variable to 0 if you are running MySQL on a system that does not have case-sensitive filenames (such as Windows or Mac OS X). New in 4.0.18: If this variable is not set at startup and the filesystem on which the data directory is located does not have case-sensitive filenames, MySQL automatically sets `lower_case_table_names` to 2.

- `max_allowed_packet`

  The maximum size of one packet or any generated/intermediate string.

  The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch big (possibly wrong) packets.

  You must increase this value if you are using big `BLOB` columns or long strings. It should be as big as the biggest `BLOB` you want to use. The protocol limit for `max_allowed_packet` is 16MB before MySQL 4.0 and 1GB thereafter.

- `max_binlog_cache_size`

  If a multiple-statement transaction requires more than this amount of memory, you get the error `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage`. This variable was added in MySQL 3.23.29.

- `max_binlog_size`

  If a write to the binary log exceeds the given value, rotate the binary logs. You cannot set this variable to more than 1GB or to less than 4096 bytes. (The minimum before MYSQL 4.0.14 is 1024 bytes.) The default value is 1GB. This variable was added in MySQL 3.23.33.

  Note if you are using transactions: A transaction is written in one chunk to the binary log, hence it is never split between several binary logs. Therefore, if you have big transactions, you might see binary logs bigger than `max_binlog_size`.

  If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well. `max_relay_log_size` was added in MySQL 4.0.14.

- `max_connect_errors`

  If there are more than this number of interrupted connections from a host, that host is blocked from further connections. You can unblock blocked hosts with the `FLUSH HOSTS` statement.

- `max_connections`

  The number of simultaneous client connections allowed. Increasing this value increases the number of file descriptors that `mysqld` requires. See Section 7.4.8, "How MySQL Opens and Closes Tables" for comments on file descriptor limits. Also see Section A.2.6, "`Too many connections`".

- `max_delayed_threads`

  Don't start more than this number of threads to handle `INSERT DELAYED` statements. If you try to insert data into a new table after all `INSERT DELAYED` threads are in use, the row is inserted as if the `DELAYED` attribute wasn't specified. If you set this to 0, MySQL never creates a

thread to handle DELAYED rows; in effect, this disables DELAYED entirely. This variable was added in MySQL 3.23.0.

- max_error_count

The maximum number of error, warning, and note messages to be stored for display by SHOW ERRORS or SHOW WARNINGS. This variable was added in MySQL 4.1.0.

- max_heap_table_size

This variable sets the maximum size to which MEMORY (HEAP) tables are allowed to grow. The value of the variable is used to calculate MEMORY table MAX_ROWS values. Setting this variable has no effect on any existing MEMORY table, unless the table is re-created with a statement such as CREATE TABLE or TRUNCATE TABLE, or altered with ALTER TABLE. This variable was added in MySQL 3.23.0.

- max_insert_delayed_threads

This variable is a synonym for max_delayed_threads. It was added in MySQL 4.0.19.

- max_join_size

Don't allow SELECT statements that probably need to examine more than max_join_size rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than max_join_size disk seeks. By setting this value, you can catch SE-LECT statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a WHERE clause, that take a long time, or that re-turn millions of rows.

Setting this variable to a value other than DEFAULT resets the SQL_BIG_SELECTS value to 0. If you set the SQL_BIG_SELECTS value again, the max_join_size variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

This variable previously was named sql_max_join_size.

- max_length_for_sort_data

The cutoff on the size of index values that determines which filesort algorithm to use. See Section 7.2.12, "How MySQL Optimizes ORDER BY". This variable was added in MySQL 4.1.1

- max_relay_log_size

If a write by a replication slave to its relay log exceeds the given value, rotate the relay log. This variable enables you to put different size constraints on relay logs and binary logs. However, set-ting the variable to 0 makes MySQL use max_binlog_size for both binary logs and relay logs. You must set max_relay_log_size to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. This variable was added in MySQL 4.0.14. See Section 6.3, "Replication Implementation Details".

- max_seeks_for_key

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning a key, regardless of the actual cardinality of the key (see Section 13.5.4.11, "SHOW INDEX Syntax"). By setting this to a low value (100?), you can force MySQL to prefer keys instead of table scans.

This variable was added in MySQL 4.0.14.

- max_sort_length

The number of bytes to use when sorting `BLOB` or `TEXT` values. Only the first `max_sort_length` bytes of each value are used; the rest are ignored.

- `max_tmp_tables`

The maximum number of temporary tables a client can keep open at the same time. (This option doesn't yet do anything.)

- `max_user_connections`

The maximum number of simultaneous connections allowed to any given MySQL account. A value of 0 means "no limit." This variable was added in MySQL 3.23.34.

Before MySQL 5.0.3, this variable has only a global form. Beginning with MySQL 5.0.3, it also has a read-only session form. The session variable has the same value as the global variable unless the current account has a non-zero `MAX_USER_CONNECTIONS` resource limit. In that case, the session value reflects the account limit.

- `max_write_lock_count`

After this many write locks, allow some read locks to run in between. This variable was added in MySQL 3.23.7.

- `multi_read_range`

Specifies the maximum number of ranges to send to a storage engine during range selects. The default value is 256. Sending multiple ranges to an engine is a feature that can improve the performance of certain selects dramatically, particularly for `NDBCLUSTER`. This engine needs to send the range requests to all nodes, and sending many of those requests at once reduces the communication costs significantly. This variable was added in MySQL 5.0.3.

- `myisam_data_pointer_size`

The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6 (4 before MySQL 5.0.6). This variable was added in MySQL 4.1.2. See Section A.2.11, "`The table is full`".

- `myisam_max_extra_sort_file_size`

If the temporary file used for fast `MyISAM` index creation would be larger than using the key cache by the amount specified here, prefer the key cache method. This is mainly used to force long character keys in large tables to use the slower key cache method to create the index. This variable was added in MySQL 3.23.37. **Note**: The value is given in megabytes before 4.0.3 and in bytes thereafter. This variable was removed in MySQL 5.0.6.

- `myisam_max_sort_file_size`

The maximum size of the temporary file MySQL is allowed to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be bigger than this value, the index is created using the key cache instead, which is slower. This variable was added in MySQL 3.23.37. **Note**: The value is given in megabytes before 4.0.3 and in bytes thereafter.

- `myisam_recover_options`

The value of the `--myisam-recover` option. This variable was added in MySQL 3.23.36.

- `myisam_repair_threads`

If this value is greater than 1, `MyISAM` table indexes are created in parallel (each index in its own thread) during the `Repair by sorting` process. The default value is 1. **Note**: Multi-threaded repair is still *alpha* quality code. This variable was added in MySQL 4.0.13.

- `myisam_sort_buffer_size`

  The buffer that is allocated when sorting `MyISAM` indexes during a `REPAIR TABLE` or when creating indexes with `CREATE INDEX` or `ALTER TABLE`. This variable was added in MySQL 3.23.16.

- `named_pipe`

  On Windows, indicates whether the server supports connections over named pipes. This variable was added in MySQL 3.23.50.

- `net_buffer_length`

  The communication buffer is reset to this size between queries. This should not normally be changed, but if you have very little memory, you can set it to the expected length of SQL statements sent by clients. If statements exceed this length, the buffer is automatically enlarged, up to `max_allowed_packet` bytes.

- `net_read_timeout`

  The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`. This variable was added in MySQL 3.23.20.

- `net_retry_count`

  If a read on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads. This variable was added in MySQL 3.23.7.

- `net_write_timeout`

  The number of seconds to wait for a block to be written to a connection before aborting the write. See also `net_read_timeout`. This variable was added in MySQL 3.23.20.

- `new`

  This variable is used in MySQL 4.0 to turn on some 4.1 behaviors. This variable was added in MySQL 4.0.12.

- `old_passwords`

  Whether the server should use pre-4.1-style passwords for MySQL user accounts. This variable was added in MySQL 4.1.1.

- `open_files_limit`

  The number of files that the operating system allows `mysqld` to open. This is the real value allowed by the system and might be different from the value you gave `mysqld` as a startup option. The value is 0 on systems where MySQL can't change the number of open files. This variable was added in MySQL 3.23.20.

- `optimizer_prune_level`

  Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans. This variable was added in MySQL 5.0.1.

- `optimizer_search_depth`

  The maximum depth of search performed by the query optimizer. Values larger than the number

of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value. If set to the maximum number of tables used in a query plus 2, the optimizer switches to the original algorithm used before MySQL 5.0.1 that performs an exhaustive search. This variable was added in MySQL 5.0.1.

- `pid_file`

  The pathname of the process ID (PID) file. This variable can be set with the `--pid-file` option. This variable was added in MySQL 3.23.23.

- `port`

  The port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

  The size of the buffer that is allocated when preloading indexes. This variable was added in MySQL 4.1.1.

- `protocol_version`

  The version of the client/server protocol used by the MySQL server. This variable was added in MySQL 3.23.18.

- `query_alloc_block_size`

  The allocation size of memory blocks that are allocated for objects created during query parsing and execution. If you have problems with memory fragmentation, it might help to increase this a bit. This variable was added in MySQL 4.0.16.

- `query_cache_limit`

  Don't cache results that are bigger than this. The default value is 1MB. This variable was added in MySQL 4.0.1.

- `query_cache_min_res_unit`

  The minimum size for blocks allocated by the query cache. The default value is 4KB. Tuning information for this variable is given in Section 5.12.3, "Query Cache Configuration". This variable is present from MySQL 4.1.

- `query_cache_size`

  The amount of memory allocated for caching query results. The default value is 0, which disables the query cache. Note that this amount of memory is allocated even if `query_cache_type` is set to 0. This variable was added in MySQL 4.0.1.

- `query_cache_type`

  Set query cache type. Setting the `GLOBAL` value sets the type for all clients that connect thereafter. Individual clients can set the `SESSION` value to affect their own use of the query cache.

Option	Description
0 or `OFF`	Don't cache or retrieve results. Note that this does not deallocate the query cache buffer. To do that, you should set `query_cache_size` to 0.
1 or `ON`	Cache all query results except for those that begin with `SELECT SQL_NO_CACHE`.
2 or `DE-MAND`	Cache results only for queries that begin with `SELECT SQL_CACHE`.

This variable was added in MySQL 4.0.3.

- `query_cache_wlock_invalidate`

Normally, when one client acquires a `WRITE` lock on a `MyISAM` table, other clients are not blocked from issuing queries for the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a `WRITE` lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect. This variable was added in MySQL 4.0.19.

- `query_prealloc_size`

The size of the persistent buffer used for query parsing and execution. This buffer is not freed between queries. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

This variable was added in MySQL 4.0.16.

- `range_alloc_block_size`

The size of blocks that are allocated when doing range optimization. This variable was added in MySQL 4.0.16.

- `read_buffer_size`

Each thread that does a sequential scan allocates a buffer of this size for each table it scans. If you do many sequential scans, you might want to increase this value. This variable was added in MySQL 4.0.3. Previously, it was named `record_buffer`.

- `read_only`

When the variable is set to `ON` for a replication slave server, it causes the slave to allow no updates except from slave threads or from users with the `SUPER` privilege. This can be useful to ensure that a slave server accepts no updates from clients. This variable was added in MySQL 4.0.14.

- `relay_log_purge`

Disables or enables automatic purging of relay logs as soon as they are not needed any more. The default value is 1 (enabled). This variable was added in MySQL 4.1.1.

- `read_rnd_buffer_size`

When reading rows in sorted order after a sort, the rows are read through this buffer to avoid disk seeks. Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries. This variable was added in MySQL 4.0.3. Previously, it was named `record_rnd_buffer`.

- `safe_show_database`

Don't show databases for which the user has no database or table privileges. This can improve security if you're concerned about people being able to see what databases other users have. See also `skip_show_database`.

This variable was removed in MySQL 4.0.5. Instead, use the `SHOW DATABASES` privilege to control access by MySQL accounts to database names.

- `secure_auth`

If the MySQL server has been started with the `--secure-auth` option, it blocks connections

from all accounts that have passwords stored in the old (pre-4.1) format. In that case, the value of this variable is ON, otherwise it is OFF.

You should enable this option if you want to prevent all usage of passwords in old format (and hence insecure communication over the network). This variable was added in MySQL 4.1.1.

Server startup fails with an error if this option is enabled and the privilege tables are in pre-4.1 format.

When used as a client-side option, the client refuses to connect to a server if the server requires a password in old format for the client account.

- `server_id`

  The value of the `--server-id` option. It is used for master and slave replication servers. This variable was added in MySQL 3.23.26.

- `shared_memory`

  Whether or not the server allows shared-memory connections. Currently, only Windows servers support this. This variable was added in MySQL 4.1.1.

- `shared_memory_base_name`

  Indicates whether or not the server allows shared-memory connections, and sets the identifier for the shared memory. This is useful when running multiple MYSQL instances on a single physical machine. Currently, only Windows servers support this. This variable was added in MySQL 4.1.0.

- `skip_external_locking`

  This is OFF if `mysqld` uses external locking. This variable was added in MySQL 4.0.3. Previously, it was named `skip_locking`.

- `skip_networking`

  This is ON if the server allows only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. On NetWare, only TCP/IP connections are supported, so do not set this variable to ON. This variable was added in MySQL 3.22.23.

- `skip_show_database`

  This prevents people from using the SHOW DATABASES statement if they don't have the SHOW DATABASES privilege. This can improve security if you're concerned about people being able to see what databases other users have. See also `safe_show_database`. This variable was added in MySQL 3.23.4. As of MySQL 4.0.2, its effect also depends on the SHOW DATABASES privilege: If the variable value is ON, the SHOW DATABASES statement is allowed only to users who have the SHOW DATABASES privilege, and the statement displays all database names. If the value is OFF, SHOW DATABASES is allowed to all users, but displays each database name only if the user has the SHOW DATABASES privilege or some privilege for the database.

- `slave_compressed_protocol`

  Whether to use compression of the slave/master protocol if both the slave and the master support it. This variable was added in MySQL 4.0.3.

- `slave_load_tmpdir`

  The name of the directory where the slave creates temporary files for replicating LOAD DATA INFILE statement. This variable was added in MySQL 4.0.0.

- `slave_net_timeout`

The number of seconds to wait for more data from a master/slave connection before aborting the read. This variable was added in MySQL 3.23.40.

- `slave_skip_errors`

The replication errors that the slave should skip (ignore). This variable was added in MySQL 3.23.47.

- `slave_transaction_retries`

If a replication slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or exceeded InnoDB's `innodb_lock_wait_timeout` or NDBCluster's `Transaction-DeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default in MySQL 4.1 is 0. You must explicitly set the value greater than 0 to enable the "retry" behavior, which is probably a good idea. In MySQL 5.0.3 or newer, the default is 10.

- `slow_launch_time`

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable. This variable was added in MySQL 3.23.15.

- `socket`

On Unix, this is the Unix socket file used for local client connections. On Windows, this is the name of the named pipe used for local client connections.

- `sort_buffer_size`

Each thread that needs to do a sort allocates a buffer of this size. Increase this value for faster `ORDER BY` or `GROUP BY` operations. See Section A.4.4, "Where MySQL Stores Temporary Files".

- `sql_mode`

The current server SQL mode. This variable was added in MySQL 3.23.41. It can be set dynamically as of MySQL 4.1.1. See Section 5.3.2, "The Server SQL Mode".

- `sql_slave_skip_counter`

The number of events from the master that a slave server should skip. It was added in MySQL 3.23.33.

- `storage_engine`

This variable is a synonym for `table_type`. It was added in MySQL 4.1.2.

- `sync_binlog`

If positive, the MySQL server synchronizes its binary log to disk (`fdatasync()`) after every `sync_binlog`'th write to this binary log. Note that there is one write to the binary log per statement if in autocommit mode, and otherwise one write per transaction. The default value is 0 which does no sync'ing to disk. A value of 1 is the safest choice, because in case of crash you lose at most one statement/transaction from the binary log; but it is also the slowest choice (unless the disk has a battery-backed cache, which makes sync'ing very fast). This variable was added in MySQL 4.1.3.

- `sync_frm`

This was added as a command-line option in MySQL 4.0.18, and is also a settable global variable since MySQL 4.1.3. If set to 1, when a non-temporary table is created it synchronizes its `.frm` file to disk (`fdatasync()`); this is slower but safer in case of crash. Default is 1.

- `system_time_zone`

  The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the `TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script. This variable was added in MySQL 4.1.3.

- `table_cache`

  The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. See Section 5.3.4, "Server Status Variables". If the value of `Opened_tables` is large and you don't do `FLUSH TABLES` a lot (which just forces all tables to be closed and reopened), then you should increase the value of the `table_cache` variable.

  For more information about the table cache, see Section 7.4.8, "How MySQL Opens and Closes Tables".

- `table_type`

  The default table type (storage engine). To set the table type at server startup, use the `--default-table-type` option. This variable was added in MySQL 3.23.0. See Section 5.3.1, "`mysqld` Command-Line Options".

- `thread_cache_size`

  How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. (Normally this doesn't give a notable performance improvement if you have a good thread implementation.) By examining the difference between the `Connections` and `Threads_created` status variables (see Section 5.3.4, "Server Status Variables" for details) you can see how efficient the thread cache is. This variable was added in MySQL 3.23.16.

- `thread_concurrency`

  On Solaris, `mysqld` calls `thr_setconcurrency()` with this value. This function allows applications to give the threads system a hint about the desired number of threads that should be run at the same time. This variable was added in MySQL 3.23.7.

- `thread_stack`

  The stack size for each thread. Many of the limits detected by the `crash-me` test are dependent on this value. The default is large enough for normal operation. See Section 7.1.4, "The MySQL Benchmark Suite".

- `time_format`

  This variable is not implemented.

- `time_zone`

  The current time zone. The initial value of this is `'SYSTEM'` (use the value of `system_time_zone`), but can be specified explicitly at server startup time with the `--default-time-zone` option. This variable was added in MySQL 4.1.3.

- `timezone`

  The time zone for the server. This is set from the `TZ` environment variable when `mysqld` is started. The time zone also can be set by giving a `--timezone` argument to `mysqld_safe`.

This variable was added in MySQL 3.23.15. As of MySQL 4.1.3, it is obsolete and has been replaced by the `system_time_zone` variable. See Section A.4.6, "Time Zone Problems".

- `tmp_table_size`

  If an in-memory temporary table exceeds this size, MySQL automatically converts it to an on-disk `MyISAM` table. Increase the value of `tmp_table_size` if you do many advanced `GROUP BY` queries and you have lots of memory.

- `tmpdir`

  The directory used for temporary files and temporary tables. Starting from MySQL 4.1, this variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (':') on Unix and semicolon characters (';') on Windows, NetWare, and OS/2.

  This feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set `tmpdir` to point to a directory on a memory-based filesystem or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. However, if you're using MySQL 4.0.0 or later, you may set the slave's temporary directory using the `slave_load_tmpdir` variable. In that case, the slave won't use the general `tmpdir` any more, which means you can set `tmpdir` to a non-permanent location then.

  This variable was added in MySQL 3.22.4.

- `transaction_alloc_block_size`

  The allocation size of memory blocks that are allocated for storing queries that are part of a transaction to be stored in the binary log when doing a commit. This variable was added in MySQL 4.0.16.

- `transaction_prealloc_size`

  The size of the persistent buffer for `transaction_alloc_blocks` that is not freed between queries. By making this big enough to fit all queries in a common transaction, you can avoid a lot of `malloc()` calls. This variable was added in MySQL 4.0.16.

- `tx_isolation`

  The default transaction isolation level. This variable was added in MySQL 4.0.3.

- `updatable_views_with_limit`

  This variable controls whether updates can be made using a view that does not contain a primary key in the underlying table, if the update contains a `LIMIT` clause. (Such updates often are generated by GUI tools.) An update is an `UPDATE` or `DELETE` statement. Primary key here means a `PRIMARY KEY`, or a `UNIQUE` index in which no column can contain `NULL`.

  The variable can have two values:

  - `1` or `YES`: Issue a warning only (not an error message). This is the default value.

  - `0` or `NO`: Prohibit the update.

  This variable was added in MySQL 5.0.2.

- `version`

  The version number for the server.

- `version_bdb`

The `BDB` storage engine version. This variable was added in MySQL 3.23.31 with the name `bdb_version` and renamed to `version_bdb` in MySQL 4.1.1.

- `version_comment`

  The `configure` script has a `--with-comment` option that allows a comment to be specified when building MySQL. This variable contains the value of that comment. This variable was added in MySQL 4.0.17.

- `version_compile_machine`

  The type of machine MySQL was built on. This variable was added in MySQL 4.1.1.

- `version_compile_os`

  The type of operating system MySQL was built on. This variable was added in MySQL 4.0.19.

- `wait_timeout`

  The number of seconds the server waits for activity on a non-interactive connection before closing it.

  On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

5.3.3.1. Dynamic System Variables

Beginning with MySQL 4.0.3, many server system variables are dynamic and can be set at runtime using `SET GLOBAL` or `SET SESSION`. You can also select their values using `SELECT`. See Section 9.4, "System Variables".

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether `GLOBAL` or `SESSION` (or both) apply.

Variable Name	Value Type	Type
`autocommit`	boolean	`SESSION`
`big_tables`	boolean	`SESSION`
`binlog_cache_size`	numeric	`GLOBAL`
`bulk_insert_buffer_size`	numeric	`GLOBAL｜SESSION`
`character_set_client`	string	`GLOBAL｜SESSION`
`character_set_connection`	string	`GLOBAL｜SESSION`
`character_set_results`	string	`GLOBAL｜SESSION`
`character_set_server`	string	`GLOBAL｜SESSION`
`collation_connection`	string	`GLOBAL｜SESSION`
`collation_server`	string	`GLOBAL｜SESSION`
`completion_type`	numeric	`GLOBAL｜SESSION`
`concurrent_insert`	boolean	`GLOBAL`
`connect_timeout`	numeric	`GLOBAL`
`convert_character_set`	string	`GLOBAL｜SESSION`
`default_week_format`	numeric	`GLOBAL｜SESSION`
`delay_key_write`	`OFF｜ON｜ALL`	`GLOBAL`
`delayed_insert_limit`	numeric	`GLOBAL`

delayed_insert_timeout	numeric	GLOBAL
delayed_queue_size	numeric	GLOBAL
div_precision_increment	numeric	GLOBAL|SESSION
engine_condition_pushdown	boolean	GLOBAL|SESSION
error_count	numeric	SESSION
expire_logs_days	numeric	GLOBAL
flush	boolean	GLOBAL
flush_time	numeric	GLOBAL
foreign_key_checks	boolean	SESSION
ft_boolean_syntax	numeric	GLOBAL
group_concat_max_len	numeric	GLOBAL|SESSION
identity	numeric	SESSION
innodb_autoextend_increment	numeric	GLOBAL
innodb_concurrency_tickets	numeric	GLOBAL
innodb_max_dirty_pages_pct	numeric	GLOBAL
innodb_max_purge_lag	numeric	GLOBAL
innodb_sync_spin_loops	numeric	GLOBAL
innodb_table_locks	boolean	GLOBAL|SESSION
innodb_thread_concurrency	numeric GLOBAL

Variables that are marked as "string" take a string value. Variables that are marked as "numeric" take a numeric value. Variables that are marked as "boolean" can be set to 0, 1, `ON` or `OFF`. Variables that are marked as "enumeration" normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumeration-valued system variables, the first enumeration value corresponds to 0. This differs from `ENUM` columns, for which the first enumeration value corresponds to 1.

5.3.4. Server Status Variables

The server maintains many status variables that provide information about its operations. You can view these variables and their values by using the `SHOW STATUS` statement:

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
…
```

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

The status variables have the following meanings. The `Com_xxx` statement counter variables were added beginning with MySQL 3.23.47. The `Qcache_xxx` query cache variables were added beginning with MySQL 4.0.1. Otherwise, variables with no version indicated have been present since at least MySQL 3.22.

- `Aborted_clients`

  The number of connections that were aborted because the client died without closing the connection properly. See Section A.2.10, "Communication Errors and Aborted Connections".

- `Aborted_connects`

  The number of tries to connect to the MySQL server that failed. See Section A.2.10, "Communication Errors and Aborted Connections".

- `Binlog_cache_disk_use`

  The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction. This variable was added in MySQL 4.1.2.

- `Binlog_cache_use`

  The number of transactions that used the temporary binary log cache. This variable was added in MySQL 4.1.2.

- `Bytes_received`

  The number of bytes received from all clients. This variable was added in MySQL 3.23.7.

- `Bytes_sent`

  The number of bytes sent to all clients. This variable was added in MySQL 3.23.7.

- `Com_xxx`

  The `Com_xxx` statement counter variables were added beginning with MySQL 3.23.47. They indicate the number of times each *xxx* statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_insert` count `DELETE` and `INSERT` statements.

  New `Com_stmt_xxx` status variables have been added in MySQL 4.1.13 or 5.0.8, respectively.

  - `Com_stmt_prepare`

  - `Com_stmt_execute`

  - `Com_stmt_fetch` (not available in versions before 5.0)

  - `Com_stmt_send_long_data`

  - `Com_stmt_reset`

  - `Com_stmt_close`

  Those variables stand for prepared statements commands. Their names refer to the `COM_xxx` command set used in the network layer; in other words: Their values are being increased whenever prepared statements API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` are also increased when one issues the following SQL statements: `PREPARE`, `EXECUTE`, or `DEALLOCATE` respectively. Additionally, the values of the older (available since MySQL 4.1.3) statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` are increased for the `PREPARE`, `EXECUTE`, and `DEALLOCATE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

  All of the `Com_stmt_xxx` variables are increased even if their argument (a prepared statement) is unknown or an error occurred during execution; in other words: Their values corres-

pond to the number of requests issued, not to the number of requests successfully completed.

- `Connections`

  The number of connection attempts (successful or not) to the MySQL server.

- `Created_tmp_disk_tables`

  The number of temporary tables on disk created automatically by the server while executing statements. This variable was added in MySQL 3.23.24.

- `Created_tmp_files`

  How many temporary files `mysqld` has created. This variable was added in MySQL 3.23.28.

- `Created_tmp_tables`

  The number of in-memory temporary tables created automatically by the server while executing statements. If `Created_tmp_disk_tables` is big, you may want to increase the `tmp_table_size` value to cause temporary tables to be memory-based instead of disk-based.

- `Delayed_errors`

  The number of rows written with `INSERT DELAYED` for which some error occurred (probably `duplicate key`).

- `Delayed_insert_threads`

  The number of `INSERT DELAYED` handler threads in use.

- `Delayed_writes`

  The number of `INSERT DELAYED` rows written.

- `Flush_commands`

  The number of executed `FLUSH` statements.

- `Handler_commit`

  The number of internal `COMMIT` statements. This variable was added in MySQL 4.0.2.

- `Handler_discover`

  The MySQL server can ask the `NDB Cluster` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of time tables have been discovered. This variable was added in MySQL 4.1.2.

- `Handler_delete`

  The number of times a row was deleted from a table.

- `Handler_read_first`

  The number of times the first entry was read from an index. If this is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed.

- `Handler_read_key`

  The number of requests to read a row based on a key. If this is high, it is a good indication that your queries and tables are properly indexed.

- `Handler_read_next`

The number of requests to read the next row in key order. This is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

The number of requests to read the previous row in key order. This read method is mainly used to optimize ORDER BY ... DESC. This variable was added in MySQL 3.23.6.

- `Handler_read_rnd`

The number of requests to read a row based on a fixed position. This is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan whole tables or you have joins that don't use keys properly.

- `Handler_read_rnd_next`

The number of requests to read the next row in the data file. This is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- `Handler_rollback`

The number of internal ROLLBACK statements. This variable was added in MySQL 4.0.2.

- `Handler_update`

The number of requests to update a row in a table.

- `Handler_write`

The number of requests to insert a row in a table.

- `Innodb_buffer_pool_pages_data`

The number of pages containing data (dirty or clean). Added in MySQL 5.0.2.

- `Innodb_buffer_pool_pages_dirty`

The number of pages currently dirty. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_pages_flushed`

The number of buffer pool pages that have been requested to be flushed. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_pages_free`

The number of free pages. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_pages_latched`

The number of latched pages in InnoDB buffer pool. These are pages currently being read or written or that can't be flushed or removed for some other reason. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_pages_misc`

The number of pages busy because they have been allocated for administrative overhead such as row locks or the adaptive hash index. This value can also be calculated as Innodb_buffer_pool_pages_total - Innodb_buffer_pool_pages_free - Innodb_buffer_pool_pages_data. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_pages_total`

Total size of buffer pool, in pages. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_read_ahead_rnd`

The number of "random" read-aheads `InnoDB` initiated. This happens when a query is to scan a large portion of a table but in random order. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_read_ahead_seq`

The number of sequential read-aheads `InnoDB` initiated. This happens when `InnoDB` does a sequential full table scan. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_read_requests`

The number of logical read requests `InnoDB` has done. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_reads`

The number of logical reads that `InnoDB` could not satisfy from buffer pool and had to do a single-page read. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_wait_free`

Normally, writes to the `InnoDB` buffer pool happen in the background. However, if it's necessary to read or create a page and no clean pages are available, it's necessary to wait for pages to be flushed first. This counter counts instances of these waits. If the buffer pool size was set properly, this value should be small. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_write_requests`

The number writes done to the `InnoDB` buffer pool. Added in MySQL 5.0.2.

- `Innodb_data_fsyncs`

The number of `fsync()` operations so far. Added in MySQL 5.0.2.

- `Innodb_data_pending_fsyncs`

The current number of pending `fsync()` operations. Added in MySQL 5.0.2.

- `Innodb_data_pending_reads`

The current number of pending reads. Added in MySQL 5.0.2.

- `Innodb_data_pending_writes`

The current number of pending writes. Added in MySQL 5.0.2.

- `Innodb_data_read`

The amount of data read so far, in bytes. Added in MySQL 5.0.2.

- `Innodb_data_reads`

The total number of data reads. Added in MySQL 5.0.2.

- `Innodb_data_writes`

The total number of data writes. Added in MySQL 5.0.2.

- `Innodb_data_written`

The amount of data written so far, in bytes. Added in MySQL 5.0.2.

- `Innodb_dblwr_writes`, `Innodb_dblwr_pages_written`

  The number of doublewrite writes that have been performed and the number of pages that have been written for this purpose. Added in MySQL 5.0.2.

- `Innodb_log_waits`

  The number of waits we had because log buffer was too small and we had to wait for it to be flushed before continuing. Added in MySQL 5.0.2.

- `Innodb_log_write_requests`

  The number of log write requests. Added in MySQL 5.0.2.

- `Innodb_log_writes`

  The number of physical writes to the log file. Added in MySQL 5.0.2.

- `Innodb_os_log_fsyncs`

  The number of fsyncs writes done to the log file. Added in MySQL 5.0.2.

- `Innodb_os_log_pending_fsyncs`

  The number of pending log file fsyncs. Added in MySQL 5.0.2.

- `Innodb_os_log_pending_writes`

  Pending log file writes. Added in MySQL 5.0.2.

- `Innodb_os_log_written`

  The number of bytes written to the log file. Added in MySQL 5.0.2.

- `Innodb_page_size`

  The compiled-in `InnoDB` page size (default 16KB). Many values are counted in pages; the page size allows them to be easily converted to bytes. Added in MySQL 5.0.2.

- `Innodb_pages_created`

  The number of pages created. Added in MySQL 5.0.2.

- `Innodb_pages_read`

  The number of pages read. Added in MySQL 5.0.2.

- `Innodb_pages_written`

  The number of pages written. Added in MySQL 5.0.2.

- `Innodb_row_lock_current_waits`

  The number of row locks currently being waited for. Added in MySQL 5.0.3.

- `Innodb_row_lock_time`

  The total time spent in acquiring row locks, in milliseconds. Added in MySQL 5.0.3.

- `Innodb_row_lock_time_avg`

  The average time to acquire a row lock, in milliseconds. Added in MySQL 5.0.3.

- `Innodb_row_lock_time_max`

The maximum time to acquire a row lock, in milliseconds. Added in MySQL 5.0.3.

• `Innodb_row_lock_waits`

The number of times a row lock had to be waited for. Added in MySQL 5.0.3.

• `Innodb_rows_deleted`

The number of rows deleted from `InnoDB` tables. Added in MySQL 5.0.2.

• `Innodb_rows_inserted`

The number of rows inserted in `InnoDB` tables. Added in MySQL 5.0.2.

• `Innodb_rows_read`

The number of rows read from `InnoDB` tables. Added in MySQL 5.0.2.

• `Innodb_rows_updated`

The number of rows updated in `InnoDB` tables. Added in MySQL 5.0.2.

• `Key_blocks_not_flushed`

The number of key blocks in the key cache that have changed but haven't yet been flushed to disk. This variable was added in MySQL 4.1.1. It used to be known as `Not_flushed_key_blocks`.

• `Key_blocks_unused`

The number of unused blocks in the key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in Section 5.3.3, "Server System Variables". This variable was added in MySQL 4.1.2. Section 5.3.3, "Server System Variables".

• `Key_blocks_used`

The number of used blocks in the key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

• `Key_read_requests`

The number of requests to read a key block from the cache.

• `Key_reads`

The number of physical reads of a key block from disk. If `Key_reads` is big, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.

• `Key_write_requests`

The number of requests to write a key block to the cache.

• `Key_writes`

The number of physical writes of a key block to disk.

• `Last_query_cost`

The total cost of the last compiled query as computed by the query optimizer. Useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. This variable was added in MySQL 5.0.1, with a default value of -

1. In MySQL 5.0.7, the default was changed to 0; also in version 5.0.7, the scope of `Last_query_cost` was changed to session rather than a global.

- `Max_used_connections`

  The maximum number of connections that have been in use simultaneously since the server started.

- `Not_flushed_delayed_rows`

  The number of rows waiting to be written in `INSERT DELAY` queues.

- `Not_flushed_key_blocks`

  The old name for `Key_blocks_not_flushed` before MySQL 4.1.1.

- `Open_files`

  The number of files that are open.

- `Open_streams`

  The number of streams that are open (used mainly for logging).

- `Open_tables`

  The number of tables that are open.

- `Opened_tables`

  The number of tables that have been opened. If `Opened_tables` is big, your `table_cache` value is probably too small.

- `Qcache_free_blocks`

  The number of free memory blocks in query cache.

- `Qcache_free_memory`

  The amount of free memory for query cache.

- `Qcache_hits`

  The number of cache hits.

- `Qcache_inserts`

  The number of queries added to the cache.

- `Qcache_lowmem_prunes`

  The number of queries that were deleted from the cache because of low memory.

- `Qcache_not_cached`

  The number of non-cached queries (not cachable, or not cached due to the `query_cache_type` setting).

- `Qcache_queries_in_cache`

  The number of queries registered in the cache.

- `Qcache_total_blocks`

The total number of blocks in the query cache.

- `Questions`

  The number of queries that have been sent to the server.

- `Rpl_status`

  The status of failsafe replication (not yet implemented).

- `Select_full_join`

  The number of joins that do not use indexes. If this value is not 0, you should carefully check the indexes of your tables. This variable was added in MySQL 3.23.25.

- `Select_full_range_join`

  The number of joins that used a range search on a reference table. This variable was added in MySQL 3.23.25.

- `Select_range`

  The number of joins that used ranges on the first table. (It's normally not critical even if this is big.) This variable was added in MySQL 3.23.25.

- `Select_range_check`

  The number of joins without keys that check for key usage after each row. (If this is not 0, you should carefully check the indexes of your tables.) This variable was added in MySQL 3.23.25.

- `Select_scan`

  The number of joins that did a full scan of the first table. This variable was added in MySQL 3.23.25.

- `Slave_open_temp_tables`

  The number of temporary tables currently open by the slave SQL thread. This variable was added in MySQL 3.23.29.

- `Slave_running`

  This is `ON` if this server is a slave that is connected to a master. This variable was added in MySQL 3.23.16.

- `Slave_retried_transactions`

  Total (since startup) number of times the replication slave SQL thread has retried transactions. This variable was added in MySQL 4.1.11 and 5.0.4.

- `Slow_launch_threads`

  The number of threads that have taken more than `slow_launch_time` seconds to create. This variable was added in MySQL 3.23.15.

- `Slow_queries`

  The number of queries that have taken more than `long_query_time` seconds. See Section 5.10.5, "The Slow Query Log".

- `Sort_merge_passes`

  The number of merge passes the sort algorithm has had to do. If this value is large, you should

consider increasing the value of the `sort_buffer_size` system variable. This variable was added in MySQL 3.23.28.

- `Sort_range`

The number of sorts that were done with ranges. This variable was added in MySQL 3.23.25.

- `Sort_rows`

The number of sorted rows. This variable was added in MySQL 3.23.25.

- `Sort_scan`

The number of sorts that were done by scanning the table. This variable was added in MySQL 3.23.25.

- `Ssl_xxx`

Variables used for SSL connections. These variables were added in MySQL 4.0.0.

- `Table_locks_immediate`

The number of times that a table lock was acquired immediately. This variable was added as of MySQL 3.23.33.

- `Table_locks_waited`

The number of times that a table lock could not be acquired immediately and a wait was needed. If this is high, and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication. This variable was added as of MySQL 3.23.33.

- `Threads_cached`

The number of threads in the thread cache. This variable was added in MySQL 3.23.17.

- `Threads_connected`

The number of currently open connections.

- `Threads_created`

The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache hit rate can be calculated as `Threads_created/Connections`. This variable was added in MySQL 3.23.31.

- `Threads_running`

The number of threads that are not sleeping.

- `Uptime`

The number of seconds the server has been up.

5.4. The MySQL Server Shutdown Process

The server shutdown process can be summarized like this:

1. The shutdown process is initiated

2. The server creates a shutdown thread if necessary

3. The server stops accepting new connections

4. The server terminates current activity

5. Storage engines are shut down or closed

6. The server exits

A more detailed description of the process follows:

1. The shutdown process is initiated.

   Server shutdown can be initiated several ways. For example, a user with the SHUTDOWN priv-
   ilege can execute a mysqladmin shutdown command. mysqladmin can be used on any
   platform supported by MySQL. Other operating system-specific shutdown initiation methods
   are possible as well: The server shuts down on Unix when it receives a SIGTERM signal. A
   server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

   Depending on how shutdown was initiated, the server might create a thread to handle the shut-
   down process. If shutdown was requested by a client, a shutdown thread is created. If shutdown
   is the result of receiving a SIGTERM signal, the signal thread might handle shutdown itself, or
   it might create a separate thread to do so. If the server tries to create a shutdown thread and
   cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the
   error log:

   ```
   Error: Can't create thread to kill server
   ```

3. The server stops accepting new connections.

   To prevent new activity from being initiated during shutdown, the server stops accepting new
   client connections. It does this by closing the network connections to which it normally listens
   for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared
   memory on Windows.

4. The server terminates current activity.

   For each thread that is associated with a client connection, the connection to the client is
   broken and the thread is marked as killed. Threads die when they notice that they are so
   marked. Threads for idle connections die quickly. Threads that currently are processing queries
   check their state periodically and take longer to die. For additional information about thread
   termination, see Section 13.5.5.3, "KILL Syntax", in particular for the instructions about killed
   REPAIR TABLE or OPTIMIZE TABLE operations on MyISAM tables.

   For threads that have an open transaction, the transaction is rolled back. Note that if a thread is
   updating a non-transactional table, an operation such as a multiple-row UPDATE or INSERT
   may leave the table partially updated, because the operation can terminate before completion.

   If the server is a master replication server, threads associated with currently connected slaves
   are treated like other client threads. That is, each one is marked as killed and exits when it next
   checks its state.

   If the server is a slave replication server, the I/O and SQL threads, if active, are stopped before
   client threads are marked as killed. The SQL thread is allowed to finish its current statement (to
   avoid causing replication problems) then stops. If the SQL thread was in the middle of a trans-
   action at this point, the transaction is rolled back.

5. Storage engines are shut down or closed.

At this stage, the table cache is flushed and all open tables are closed.

Each storage engine performs any actions necessary for tables that it manages. For example, MyISAM flushes any pending index writes for a table. InnoDB flushes its buffer pool to disk (starting from 5.0.5: unless `innodb_fast_shutdown` is 2), writes the current LSN to the tablespace, and terminates its own internal threads.

6. The server exits.

5.5. General Security Issues

This section describes some general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see Section 5.6, "The MySQL Access Privilege System".

5.5.1. General Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, we emphasize the necessity of fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also some support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines whenever possible:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` database!** This is critical. **The encrypted password is the real password in MySQL.** Anyone who knows the password that is listed in the `user` table and has access to the host listed for the account **can easily log in as that user**.

- Learn the MySQL access privilege system. The GRANT and REVOKE statements are used for controlling access to MySQL. Do not grant any more privileges than necessary. Never grant privileges to all hosts.

  Checklist:

  - Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, you have problems. Anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See Section 2.9.3, "Securing the Initial MySQL Accounts".

  - Use the SHOW GRANTS statement and check to see who has access to what. Then use the REVOKE statement to remove those privileges that are not necessary.

- Do not store any plain-text passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use MD5(), SHA1(), or some other one-way hashing function.

- Do not choose passwords from dictionaries. There are special programs to break them. Even passwords like "xfish98" are very bad. Much better is "duag98" which contains the same word "fish" but typed one key to the left on a standard QWERTY keyboard. Another method is to use

"Mhall" which is taken from the first characters of each word in the sentence "Mary had a little lamb." This is easy to remember and type, but difficult to guess for someone who does not know it.

- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

  Checklist:

  - Try to scan your ports from the Internet using a tool such as `nmap`. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. Another simple way to check whether or not your MySQL port is open is to try the following command from some remote machine, where `server_host` is the host on which your MySQL server runs:

    ```
    shell> telnet server_host 3306
    ```

    If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open. If `telnet` just hangs or the connection is refused, everything is OK; the port is blocked.

- Do not trust any data entered by users of your applications. They can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like "`; DROP DATABASE mysql;`". This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

  A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every record in the table. This exposes every record and causes excessive server load. The simplest way to protect from this type of attack is to use apostrophes around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In numeric context, MySQL automatically converts this string to a number and strips any trailing non-numeric characters from it.

  Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is allowable to display any record in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

  Checklist:

  - Try to enter '`'`' and '`"`' in all your Web forms. If you get any kind of MySQL error, investigate the problem right away.

  - Try to modify any dynamic URLs by adding `%22` ('`"`'), `%23` ('`#`'), and `%27` ('`'`') in the URL.

  - Try to modify data types in dynamic URLs from numeric ones to character ones containing characters from previous examples. Your application should be safe against this and similar attacks.

  - Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!

  - Check data sizes before passing them to MySQL.

  - Consider having your application connect to the database using a different username than the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

- Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

  - MySQL C API: Use the `mysql_real_escape_string()` API call.

  - MySQL++: Use the `escape` and `quote` modifiers for query streams.

  - PHP: Use the `mysql_escape_string()` function, which is based on the function of the same name in the MySQL C API. Prior to PHP 4.0.3, use `addslashes()` instead.

  - Perl DBI: Use the `quote()` method or use placeholders.

  - Java JDBC: Use a `PreparedStatement` object and placeholders.

  Other programming interfaces might have similar capabilities.

- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections as of Version 4.0.0. SSH port-forwarding can be used to create an encrypted (and compressed) tunnel for the communication.

- Learn to use the `tcpdump` and `strings` utilities. For most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

  ```
  shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
  ```

  (This works under Linux and should work with small modifications under other systems.) Warning: If you do not see plaintext data, this doesn't always mean that the information actually is encrypted. If you need high security, you should consult with a security expert.

5.5.2. Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted in clear text over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are using an older version of MySQL, or are still using pre-4.1.1-style passwords, the encryption algorithm is less strong and with some effort a clever attacker who can sniff the traffic between the client and the server can crack the password. (See Section 5.6.9, "Password Hashing in MySQL 4.1" for a discussion of the different password handling methods.) If the connection between the client and the server goes through an untrusted network, you should use an SSH tunnel to encrypt the communication.

All other information is transferred as text that can be read by anyone who is able to watch the connection. If you are concerned about this, you can use the compressed protocol (in MySQL 3.22 and above) to make traffic much more difficult to decipher. To make the connection even more secure, you should use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at http://www.openssh.org/, and a commercial SSH client at http://www.ssh.com/.

If you are using MySQL 4.0 or newer, you can also use internal OpenSSL support. See Section 5.7.7, "Using Secure Connections".

To make a MySQL system secure, you should strongly consider the following suggestions:

- Use passwords for all MySQL users. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any username to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if *other_user* has no password. If all users have a password, connecting using another user's ac-

count becomes much more difficult.

To change the password for a user, use the `SET PASSWORD` statement. It is also possible to update the `user` table in the `mysql` database directly. For example, to change the password of all MySQL accounts that have a username of `root`, do this:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password=PASSWORD('newpwd')
    -> WHERE User='root';
mysql> FLUSH PRIVILEGES;
```

- Don't run the MySQL server as the Unix `root` user. This is very dangerous, because any user with the `FILE` privilege is able to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using a `--user=root` option.

  `mysqld` can be run as an ordinary unprivileged user instead. You can also create a separate Unix account named `mysql` to make everything even more secure. Use the account only for administering MySQL. To start `mysqld` as another Unix user, add a `user` option that specifies the username to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

  ```
  [mysqld]
  user=mysql
  ```

  This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see Section A.3.2, "How to Run MySQL as a Normal User".

  Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` username in the `user` table. Usernames for MySQL accounts have nothing to do with usernames for Unix accounts.

- Don't allow the use of symlinks to tables. (This can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See Section 7.6.1.2, "Using Symbolic Links for Tables on Unix".

- Make sure that the only Unix user with read or write privileges in the database directories is the user that `mysqld` runs as.

- Don't grant the `PROCESS` or `SUPER` privilege to non-administrative users. The output of `mysqladmin processlist` shows the text of the currently executing queries, so any user who is allowed to execute that command might be able to see if another user issues an `UPDATE user SET password=PASSWORD('not_secure')` query.

  `mysqld` reserves an extra connection for users who have the `SUPER` privilege (`PROCESS` before MySQL 4.0.2), so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

  The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Don't grant the `FILE` privilege to non-administrative users. Any user that has this privilege can write a file anywhere in the filesystem with the privileges of the `mysqld` daemon! To make this a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

  The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

- If you don't trust your DNS, you should use IP numbers rather than hostnames in the grant tables. In any case, you should be very careful about creating grant table entries using hostname values that contain wildcards!

- If you want to restrict the number of connections allowed to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `GRANT` statement also supports resource control options for limiting the extent of server use allowed to an account.

5.5.3. Startup Options for `mysqld` Concerning Security

The following `mysqld` options affect security:

- `--allow-suspicious-udfs`

  This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded. This prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. This option was added in MySQL 4.0.24, 4.1.10a, and 5.0.3. See Section 25.2.3.6, "User-defined Function Security Precautions".

- `--local-infile[={0|1}]`

  If you start the server with `--local-infile=0`, clients cannot use `LOCAL` in `LOAD DATA` statements. See Section 5.5.4, "Security Issues with `LOAD DATA LOCAL`".

- `--old-passwords`

  Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See Section 5.6.9, "Password Hashing in MySQL 4.1".

- `--safe-show-database`

  With this option, the `SHOW DATABASES` statement displays the names of only those databases for which the user has some kind of privilege. As of MySQL 4.0.2, this option is deprecated and doesn't do anything (it is enabled by default), because there is a `SHOW DATABASES` privilege that can be used to control access to database names on a per-account basis. See Section 13.5.1.3, "`GRANT` and `REVOKE` Syntax".

- `--safe-user-create`

  If this is enabled, a user cannot create new users with the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table. If you want a user to have the ability to create new users with those privileges that the user has right to grant, you should grant the user the following privilege:

  ```
  mysql> GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
  ```

  This ensures that the user can't change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth`

  Disallow authentication for accounts that have old (pre-4.1) passwords. This option is available as of MySQL 4.1.1.

- `--skip-grant-tables`

  This option causes the server not to use the privilege system at all. This gives everyone *full access* to all databases! (You can tell a running server to start using the grant tables again by ex-

ecuting a `mysqladmin flush-privileges` or `mysqladmin reload` command, or by issuing a `FLUSH PRIVILEGES` statement.)

- `--skip-name-resolve`

  Hostnames are not resolved. All `Host` column values in the grant tables must be IP numbers or `localhost`.

- `--skip-networking`

  Don't allow TCP/IP connections over the network. All connections to `mysqld` must be made via Unix socket files. This option is unsuitable when using a MySQL version prior to 3.23.27 with the MIT-pthreads package, because Unix socket files were not supported by MIT-pthreads at that time.

- `--skip-show-database`

  With this option, the `SHOW DATABASES` statement is allowed only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. Without this option, `SHOW DATABASES` is allowed to all users, but displays each database name only if the user has the `SHOW DATABASES` privilege or some privilege for the database.

5.5.4. Security Issues with `LOAD DATA LOCAL`

The `LOAD DATA` statement can load a file that is located on the server host, or it can load a file that is located on the client host when the `LOCAL` keyword is specified.

There are two potential security issues with supporting the `LOCAL` version of `LOAD DATA` statements:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD DATA` statement. Such a server could access any file on the client host to which the client user has read access.

- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any command against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not the program being run by the user connecting to the Web server.

To deal with these problems, we changed how `LOAD DATA LOCAL` is handled as of MySQL 3.23.49 and MySQL 4.0.2 (4.0.13 on Windows):

- By default, all MySQL clients and libraries in binary distributions are compiled with the `--enable-local-infile` option, to be compatible with MySQL 3.23.48 and before.

- If you build MySQL from source but don't use the `--enable-local-infile` option to `configure`, `LOAD DATA LOCAL` cannot be used by any client unless it is written explicitly to invoke `mysql_options(... MYSQL_OPT_LOCAL_INFILE, 0)`. See Section 23.2.3.44, "`mysql_options()`".

- You can disable all `LOAD DATA LOCAL` commands from the server side by starting `mysqld` with the `--local-infile=0` option.

- For the `mysql` command-line client, `LOAD DATA LOCAL` can be enabled by specifying the `--local-infile[=1]` option, or disabled with the `--local-infile=0` option. Similarly, for `mysqlimport`, the `--local` or `-L` option enables local data file loading. In any case, successful use of a local loading operation requires that the server is enabled to allow it.

- If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add the `local-infile=1` option to that group. However, to keep this from causing problems for programs that do not understand `local-infile`, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=1
```

  The `loose-` prefix can be used as of MySQL 4.0.2.

- If `LOAD DATA LOCAL INFILE` is disabled, either in the server or the client, a client that attempts to issue such a statement receives the following error message:

```
ERROR 1148: The used command is not allowed with this MySQL version
```

5.6. The MySQL Access Privilege System

MySQL has an advanced but non-standard security and privilege system. This section describes how it works.

5.6.1. What the Privilege System Does

The primary function of the MySQL privilege system is to authenticate a user connecting from a given host, and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`.

Additional functionality includes the ability to have anonymous users and to grant privileges for MySQL-specific functions such as `LOAD DATA INFILE` and administrative operations.

5.6.2. How the Privilege System Works

The MySQL privilege system ensures that all users may perform only the operations allowed to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the username you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your hostname and username in identifying you because there is little reason to assume that a given username belongs to the same person everywhere on the Internet. For example, the user `joe` who connects from `office.com` need not be the same person as the user `joe` who connects from `elsewhere.com`. MySQL handles this by allowing you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by `joe` from `office.com`, and a different set of privileges for connections by `joe` from `elsewhere.com`.

MySQL access control involves two stages:

- Stage 1: The server checks whether it should allow you to connect.

- Stage 2: Assuming that you can connect, the server checks each statement you issue to see whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the `SELECT` privilege for the table or the `DROP` privilege for the database.

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement you issue. See Section 5.6.7, "When Privilege Changes Take Effect" for details.

The server stores privilege information in the grant tables of the `mysql` database (that is, in the database named `mysql`). The MySQL server reads the contents of these tables into memory when it starts and re-reads them under the circumstances indicated in Section 5.6.7, "When Privilege Changes Take Effect". Access-control decisions are based on the in-memory copies of the grant tables.

Normally, you manipulate the contents of the grant tables indirectly by using the `GRANT` and `RE-VOKE` statements to set up accounts and control the privileges available to each one. See Section 13.5.1.3, "`GRANT` and `REVOKE` Syntax". The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients.

The server uses the `user`, `db`, and `host` tables in the `mysql` database at both stages of access control. The columns in these grant tables are shown here:

Table Name	user	db	host
Scope columns	Host	Host	Host
	User	Db	Db
	Password	User	
Privilege columns	Select_priv	Select_priv	Select_priv
	Insert_priv	Insert_priv	Insert_priv
	Update_priv	Update_priv	Update_priv
	Delete_priv	Delete_priv	Delete_priv
	Index_priv	Index_priv	Index_priv
	Alter_priv	Alter_priv	Alter_priv
	Create_priv	Create_priv	Create_priv
	Drop_priv	Drop_priv	Drop_priv
	Grant_priv	Grant_priv	Grant_priv
	Create_view_priv	Create_view_priv	Create_view_priv
	Show_view_priv	Show_view_priv	Show_view_priv
	Create_routine_priv	Create_routine_priv	
	Alter_routine_priv	Alter_routine_priv	
	References_priv	References_priv	References_priv
	Reload_priv		
	Shutdown_priv		
	Process_priv		
	File_priv		
	Show_db_priv		
	Super_priv		
	Create_tmp_table_priv	Create_tmp_table_priv	Create_tmp_table_priv
	Lock_tables_priv	Lock_tables_priv	Lock_tables_priv
	Execute_priv		
	Repl_slave_priv		
	Repl_client_priv		
Security columns	ssl_type		
	ssl_cipher		
	x509_issuer		

	x509_subject		
Resource control columns	max_questions		
	max_updates		
	max_connections		
	max_user_connect ions		

The `ssl_type`, `ssl_cipher`, `x509_issuer`, and `x509_subject` columns were added in MySQL 4.0.0.

The `Create_tmp_table_priv`, `Execute_priv`, `Lock_tables_priv`, `Repl_client_priv`, `Repl_slave_priv`, `Show_db_priv`, `Super_priv`, `max_questions`, `max_updates`, and `max_connections` columns were added in MySQL 4.0.2. `Execute_priv` is not operational until MySQL 5.0.3, however.

The `Create_view_priv` and `Show_view_priv` columns were added in MySQL 5.0.1.

The `Create_routine_priv`, `Alter_routine_priv`, and `max_user_connections` columns were added in MySQL 5.0.3.

During the second stage of access control, the server performs request verification to make sure that each client has sufficient privileges for each request that it issues. In addition to the `user`, `db`, and `host` grant tables, the server may also consult the `tables_priv` and `columns_priv` tables for requests that involve tables. The `tables_priv` and `columns_priv` tables provide finer privilege control at the table and column levels. They have the following columns:

Table Name	tables_priv	columns_priv
Scope columns	Host	Host
	Db	Db
	User	User
	Table_name	Table_name
		Column_name
Privilege columns	Table_priv	Column_priv
	Column_priv	
Other columns	Timestamp	Timestamp
	Grantor	

The `Timestamp` and `Grantor` columns currently are unused and are discussed no further here.

For verification of requests that involve stored routines, the server may consult the `procs_priv` table. This table has the following columns:

Table Name	procs_priv
Scope columns	Host
	Db
	User
	Routine_name
	Routine_type
Privilege columns	Proc_priv
Other columns	Timestamp
	Grantor

The `procs_priv` table exists as of MySQL 5.0.3. The `Routine_type` column was added in MySQL 5.0.6. It is an `ENUM` column with values of `'FUNCTION'` or `'PROCEDURE'` to indicate the type of routine the row refers to. This column allows privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns currently are unused and are discussed no further here.

Each grant table contains scope columns and privilege columns:

• Scope columns determine the scope of each entry (row) in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of `'thomas.loc.gov'` and `'bob'` would be used for authenticating connections made to the server from the host `thomas.loc.gov` by a client that specifies a username of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of `'thomas.loc.gov'`, `'bob'` and `'reports'` would be used when `bob` connects from the host `thomas.loc.gov` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the store routine to which each row applies.

• Privilege columns indicate which privileges are granted by a table row; that is, what operations can be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. The rules used to do this are described in Section 5.6.6, "Access Control, Stage 2: Request Verification".

Scope columns contain strings. They are declared as shown here; the default value for each is the empty string:

Column Name	Type
Host	CHAR(60)
User	CHAR(16)
Password	CHAR(16)
Db	CHAR(64)
Table_name	CHAR(64)
Column_name	CHAR(64)
Routine_name	CHAR(64)

Before MySQL 3.23, the `Db` column is `CHAR(32)` in some tables and `CHAR(60)` in others.

For access-checking purposes, comparisons of `Host` values are case-insensitive. `User`, `Password`, `Db`, and `Table_name` values are case sensitive. `Column_name` values are case insensitive in MySQL 3.22.12 or later.

In the `user`, `db`, and `host` tables, each privilege is listed in a separate column that is declared as `ENUM('N','Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

In the `tables_priv`, `columns_priv`, and `procs_priv` tables, the privilege columns are declared as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table:

Table Name	Column Name	Possible Set Elements
tables_priv	Table_priv	'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter'
tables_priv	Column_priv	'Select', 'Insert', 'Update', 'References'
columns_pri	Column_priv	'Select', 'Insert', 'Update', 'References'

v		
procs_priv	Proc_priv	'Execute', 'Alter Routine', 'Grant'

Briefly, the server uses the grant tables as follows:

- The user table scope columns determine whether to reject or allow incoming connections. For allowed connections, any privileges granted in the user table indicate the user's global (superuser) privileges. These privileges apply to *all* databases on the server.

- The db table scope columns determine which users can access which databases from which hosts. The privilege columns determine which operations are allowed. A privilege granted at the database level applies to the database and to all its tables.

- The host table is used in conjunction with the db table when you want a given db table row to apply to several hosts. For example, if you want a user to be able to use a database from several hosts in your network, leave the Host value empty in the user's db table row, then populate the host table with a row for each of those hosts. This mechanism is described more detail in Section 5.6.6, "Access Control, Stage 2: Request Verification".

  Note: The host table is not affected by the GRANT and REVOKE statements. Most MySQL installations need not use this table at all.

- The tables_priv and columns_priv tables are similar to the db table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.

- The procs_priv table applies to stored routines. A privilege granted at the routine level applies only to a single routine.

Administrative privileges (such as RELOAD or SHUTDOWN) are specified only in the user table. This is because administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. In fact, to determine whether you can perform an administrative operation, the server need consult only the user table.

The FILE privilege also is specified only in the user table. It is not an administrative privilege as such, but your ability to read or write files on the server host is independent of the database you are accessing.

The mysqld server reads the contents of the grant tables into memory when it starts. You can tell it to re-read the tables by issuing a FLUSH PRIVILEGES statement or executing a mysqladmin flush-privileges or mysqladmin reload command. Changes to the grant tables take effect as indicated in Section 5.6.7, "When Privilege Changes Take Effect".

When you modify the contents of the grant tables, it is a good idea to make sure that your changes set up privileges the way you want. To check the privileges for a given account, use the SHOW GRANTS statement. For example, to determine the privileges that are granted to an account with Host and User values of pc84.example.com and bob, issue this statement:

mysql> **SHOW GRANTS FOR 'bob'@'pc84.example.com';**

A useful diagnostic tool is the mysqlaccess script, which Yves Carlier has provided for the MySQL distribution. Invoke mysqlaccess with the --help option to find out how it works. Note that mysqlaccess checks access using only the user, db, and host tables. It does not check table, column, or routine privileges specified in the tables_priv, columns_priv, or procs_priv tables.

For additional help in diagnosing privilege-related problems, see Section 5.6.8, "Causes of Access denied Errors". For general advice on security issues, see Section 5.5, "General Security Issues".

5.6.3. Privileges Provided by MySQL

Information about account privileges is stored in the user, db, host, tables_priv, columns_priv, and procs_priv tables in the mysql database. The MySQL server reads the contents of these tables into memory when it starts and re-reads them under the circumstances indicated in Section 5.6.7, "When Privilege Changes Take Effect". Access-control decisions are based on the in-memory copies of the grant tables.

The names used in the GRANT and REVOKE statements to refer to privileges are shown in the following table, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies. Further information about the meaning of each privilege may be found at Section 13.5.1.3, "GRANT and REVOKE Syntax".

Privilege	Column	Context
CREATE	Create_priv	databases, tables, or indexes
DROP	Drop_priv	databases or tables
GRANT OPTION	Grant_priv	databases, tables, or stored routines
REFERENCES	References_priv	databases or tables
ALTER	Alter_priv	tables
DELETE	Delete_priv	tables
INDEX	Index_priv	tables
INSERT	Insert_priv	tables
SELECT	Select_priv	tables
UPDATE	Update_priv	tables
CREATE VIEW	Create_view_priv	views
SHOW VIEW	Show_view_priv	views
ALTER ROUTINE	Alter_routine_priv	stored routines
CREATE ROUTINE	Create_routine_priv	stored routines
EXECUTE	Execute_priv	stored routines
FILE	File_priv	file access on server host
CREATE TEMPORARY TABLES	Create_tmp_table_priv	server administration
LOCK TABLES	Lock_tables_priv	server administration
CREATE USER	Create_user_priv	server administration
PROCESS	Process_priv	server administration
RELOAD	Reload_priv	server administration
REPLICATION CLIENT	Repl_client_priv	server administration
REPLICATION SLAVE	Repl_slave_priv	server administration
SHOW DATABASES	Show_db_priv	server administration
SHUTDOWN	Shutdown_priv	server administration
SUPER	Super_priv	server administration

The CREATE TEMPORARY TABLES, EXECUTE, LOCK TABLES, REPLICATION CLIENT, REPLICATION SLAVE, SHOW DATABASES, and SUPER privileges were added in MySQL 4.0.2. (EXECUTE is not operational until MySQL 5.0.3.) CREATE VIEW and SHOW VIEW were added in MySQL 5.0.1. CREATE USER, CREATE ROUTINE, and ALTER ROUTINE were added in MySQL 5.0.3. To use these privileges when upgrading from an earlier version of MySQL that does not have them, you must upgrade your grant tables. See Section 2.10.8, "Upgrading the Grant Tables".

To create or alter stored routines if binary logging is enabled, you may also need the `SUPER` privilege, as described in Section 18.4, "Binary Logging of Stored Routines and Triggers".

The `CREATE` and `DROP` privileges allow you to create new databases and tables, or to drop (remove) existing databases and tables. If you grant the `DROP` privilege for the `mysql` database to a user, that user can drop the database in which the MySQL access privileges are stored!

The `SELECT`, `INSERT`, `UPDATE`, and `DELETE` privileges allow you to perform operations on rows in existing tables in a database.

`SELECT` statements require the `SELECT` privilege only if they actually retrieve rows from a table. Some `SELECT` statements do not access tables and can be executed without permission for any database. For example, you can use the `mysql` client as a simple calculator to evaluate expressions that make no reference to tables:

```
mysql> SELECT 1+1;
mysql> SELECT PI()*2;
```

The `INDEX` privilege allows you to create or drop (remove) indexes. `INDEX` applies to existing tables. If you have the `CREATE` privilege for a table, you can include index definitions in the `CREATE TABLE` statement.

The `ALTER` privilege allows you to use `ALTER TABLE` to change the structure of or rename tables.

The `CREATE ROUTINE` privilege is needed for creating stored routines (functions and procedures). `ALTER ROUTINE` privilege is needed for altering or dropping stored routines, and `EXECUTE` is needed for executing stored routines.

The `GRANT` privilege allows you to give to other users those privileges that you yourself possess. It can be used for databases, tables, and stored routines.

The `FILE` privilege gives you permission to read and write files on the server host using the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements. A user who has the `FILE` privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.) The `FILE` privilege also allows the user to create new files in any directory where the MySQL server has write access. Existing files cannot be overwritten.

The remaining privileges are used for administrative operations. Many of them can be performed by using the `mysqladmin` program or by issuing SQL statements. The following table shows which `mysqladmin` commands each administrative privilege allows you to execute:

Privilege	Commands Permitted to Privilege Holders
RELOAD	`flush-hosts, flush-logs, flush-privileges, flush-status, flush-tables, flush-threads, refresh, reload`
SHUTDOWN	`shutdown`
PROCESS	`processlist`
SUPER	`kill`

The `reload` command tells the server to re-read the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

The `shutdown` command shuts down the server. This command can be issued only from `mysqladmin`. There is no corresponding SQL statement.

The `processlist` command displays information about the threads executing within the server (that is, about the statements being executed by clients associated with other accounts). The `kill`

command terminates server threads. You can always display or kill your own threads, but you need the PROCESS privilege to display threads initiated by other users and the SUPER privilege to kill them. See Section 13.5.5.3, "KILL Syntax". Prior to MySQL 4.0.2 when SUPER was introduced, the PROCESS privilege controls the ability to both see and terminate threads for other clients.

The CREATE TEMPORARY TABLES privilege allows the use of the keyword TEMPORARY in CREATE TABLE statements.

The LOCK TABLES privilege allows the use of explicit LOCK TABLES statements to lock tables for which you have the SELECT privilege. This includes the use of write locks, which prevents anyone else from reading the locked table.

The REPLICATION CLIENT privilege allows the use of SHOW MASTER STATUS and SHOW SLAVE STATUS.

The REPLICATION SLAVE privilege should be granted to accounts that are used by slave servers to connect to the current server as their master. Without this privilege, the slave cannot request updates that have been made to databases on the master server.

The SHOW DATABASES privilege allows the account to see database names by issuing the SHOW DATABASE statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the --skip-show-database option.

It is a good idea in general to grant to an account only those privileges that it needs. You should exercise particular caution in granting the FILE and administrative privileges:

- The FILE privilege can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using SELECT to transfer its contents to the client host.

- The GRANT privilege allows users to give their privileges to other users. Two users with different privileges and with the GRANT privilege are able to combine privileges.

- The ALTER privilege may be used to subvert the privilege system by renaming tables.

- The SHUTDOWN privilege can be abused to deny service to other users entirely by terminating the server.

- The PROCESS privilege can be used to view the plain text of currently executing queries, including queries that set or change passwords.

- The SUPER privilege can be used to terminate other clients or change how the server operates.

- Privileges granted for the mysql database itself can be used to change passwords and other access privilege information. Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the user table Password column can change an account's password, and then connect to the MySQL server using that account.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.

- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.

5.6.4. Connecting to the MySQL Server

MySQL client programs generally expect you to specify connection parameters when you want to access a MySQL server:

- The name of the host where the MySQL server is running

- Your username

- Your password

For example, the `mysql` client can be started as follows from a command-line prompt (indicated here by `shell>`):

```
shell> mysql -h host_name -u user_name -pyour_pass
```

Alternate forms of the `-h`, `-u`, and `-p` options are `--host=host_name`, `--user=user_name`, and `--password=your_pass`. Note that there is *no space* between `-p` or `--password=` and the password following it.

If you use a `-p` or `--password` option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Any user on your system may be able to see a password specified on the command line by executing a command such as `ps auxww`. See Section 5.7.6, "Keeping Your Password Secure".

MySQL client programs use default values for any connection parameter option that you do not specify:

- The default hostname is `localhost`.

- The default username is `ODBC` on Windows and your Unix login name on Unix.

- No password is supplied if `-p` is missing.

Thus, for a Unix user with a login name of `joe`, all of the following commands are equivalent:

```
shell> mysql -h localhost -u joe
shell> mysql -h localhost
shell> mysql -u joe
shell> mysql
```

Other MySQL clients behave similarly.

You can specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

-
   You can specify connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

   ```
   [client]
   host=host_name
   user=user_name
   password=your_pass
   ```

   Option files are discussed further in Section 4.3.2, "Using Option Files".

- You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL username can be specified using `USER` (this is for Windows and NetWare only). The password can be specified using `MYSQL_PWD`, although this is insecure; see Section 5.7.6, "Keeping Your Password Secure". For a list of variables, see Appendix G, *Environment Variables*.

5.6.5. Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password. If not, the server denies access to you completely. Otherwise, the server accepts the connection, then enters Stage 2 and waits for requests.

Your identity is based on two pieces of information:

- The client host from which you connect

- Your MySQL username

Identity checking is performed using the three `user` table scope columns (`Host`, `User`, and `Password`). The server accepts the connection only if the `Host` and `User` columns in some `user` table record match the client hostname and username, and the client supplies the password specified in that record.

`Host` values in the `user` table may be specified as follows:

- A `Host` value may be a hostname or an IP number, or `'localhost'` to indicate the local host.

- You can use the wildcard characters '`%`' and '`_`' in `Host` column values. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a `Host` value of `'%'` matches any hostname, whereas a value of `'%.mysql.com'` matches any host in the `mysql.com` domain.

-
  As of MySQL 3.23, for `Host` values specified as IP numbers, you can specify a netmask indicating how many address bits to use for the network number. For example:

  ```
  mysql> GRANT ALL PRIVILEGES ON db.*
      -> TO david@'192.58.197.0/255.255.255.0';
  ```

  This allows `david` to connect from any client host having an IP number `client_ip` for which the following condition is true:

  ```
  client_ip & netmask = host_ip
  ```

  That is, for the `GRANT` statement just shown:

  ```
  client_ip & 255.255.255.0 = 192.58.197.0
  ```

  IP numbers that satisfy this condition and can connect to the MySQL server are those that lie in the range from `192.58.197.0` to `192.58.197.255`.

- Note: The netmask can only be used to tell the server to use 8, 16, 24, or 32 bits of the address, for example:

  ```
  192.0.0.0/255.0.0.0 (anything on the 192 class A network)
  ```

```
192.168.0.0/255.255.0.0 (anything on the 192.168 class B network)
192.168.1.0/255.255.255.0 (anything on the 192.168.1 class C network)
192.168.1.1 (only this specific IP)
```

The following netmask (28 bits) will not work:

```
192.168.0.1/255.255.255.240
```

- A blank `Host` value in a `db` table record means that its privileges should be combined with those in the row in the `host` table that matches the client hostname. The privileges are combined using an AND (intersection) operation, not OR (union). You can find more information about the `host` table in Section 5.6.6, "Access Control, Stage 2: Request Verification".

  A blank `Host` value in the other grant tables is the same as `'%'`.

Because you can use IP wildcard values in the `Host` column (for example, `'144.155.166.%'` to match every host on a subnet), someone could try to exploit this capability by naming a host `144.155.166.somewhere.com`. To foil such attempts, MySQL disallows matching on hostnames that start with digits and a dot. Thus, if you have a host named something like `1.2.foo.com`, its name never matches the `Host` column of the grant tables. An IP wildcard value can match only IP numbers, not hostnames.

In the `User` column, wildcard characters are not allowed, but you can specify a blank value, which matches any name. If the `user` table row that matches an incoming connection has a blank username, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank username is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `Password` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password.

Non-blank `Password` values in the `user` table represent encrypted passwords. MySQL does not store passwords in plaintext form for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the `PASSWORD()` function). The encrypted password then is used during the connection process when checking whether the password is correct. (This is done without the encrypted password ever traveling over the connection.) From MySQL's point of view, the encrypted password is the REAL password, so you should not give anyone access to it! In particular, don't give non-administrative users read access to the tables in the `mysql` database!

From version 4.1 on, MySQL employs a stronger authentication method that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the `mysql` database is captured. Password encryption is discussed further in Section 5.6.9, "Password Hashing in MySQL 4.1".

The following examples show how various combinations of `Host` and `User` values in the `user` table apply to incoming connections:

Host **Value**	User **Value**	**Connections Matched by Entry**
`'thomas.loc.gov'`	`'fred'`	`fred`, connecting from `thomas.loc.gov`
`'thomas.loc.gov'`	`''`	Any user, connecting from `thomas.loc.gov`
`'%'`	`'fred'`	`fred`, connecting from any host
`'%'`	`''`	Any user, connecting from any host
`'%.loc.gov'`	`'fred'`	`fred`, connecting from any host in the `loc.gov` domain
`'x.y.%'`	`'fred'`	`fred`, connecting from `x.y.net`, `x.y.com`, `x.y.edu`, and so on. (this is probably not useful)

'144.155.166.177'	'fred'	`fred`, connecting from the host with IP address `144.155.166.177`
'144.155.166.%'	'fred'	`fred`, connecting from any host in the `144.155.166` class C subnet
'144.155.166.0/255.255.255.0'	'fred'	Same as previous example

It is possible for the client hostname and username of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `thomas.loc.gov` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the entries.

- When a client attempts to connect, the server looks through the entries in sorted order.

- The server uses the first row that matches the client hostname and username.

To see how this works, suppose that the `user` table looks like this:

```
+-----------+----------+-
| Host      | User     | ...
+-----------+----------+-
| %         | root     | ...
| %         | jeffrey  | ...
| localhost | root     | ...
| localhost |          | ...
+-----------+----------+-
```

When the server reads in the table, it orders the entries with the most-specific `Host` values first. Literal hostnames and IP numbers are the most specific. The pattern `'%'` means "any host" and is least specific. Entries with the same `Host` value are ordered with the most-specific `User` values first (a blank `User` value means "any user" and is least specific). For the `user` table just shown, the result after sorting looks like this:

```
+-----------+----------+-
| Host      | User     | ...
+-----------+----------+-
| localhost | root     | ...
| localhost |          | ...
| %         | jeffrey  | ...
| %         | root     | ...
+-----------+----------+-
```

When a client attempts to connect, the server looks through the sorted entries and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the entries in the table match: the one with `Host` and `User` values of `'localhost'` and `''`, and the one with values of `'%'` and `'jeffrey'`. The `'localhost'` row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

```
+----------------+----------+-
| Host           | User     | ...
+----------------+----------+-
| %              | jeffrey  | ...
| thomas.loc.gov |          | ...
```

```
+----------------+----------+-
```

The sorted table looks like this:

```
+----------------+----------+-
| Host           | User     | ...
+----------------+----------+-
| thomas.loc.gov |          | ...
| %              | jeffrey  | ...
+----------------+----------+-
```

A connection by `jeffrey` from `thomas.loc.gov` is matched by the first row, whereas a connection by `jeffrey` from `whitehouse.gov` is matched by the second.

It is a common misconception to think that, for a given username, all entries that explicitly name that user are used first when the server attempts to find a match for the connection. This is simply not true. The previous example illustrates this, where a connection from `thomas.loc.gov` by `jeffrey` is first matched not by the row containing `'jeffrey'` as the `User` column value, but by the row with no username. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a username when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table record. Suppose that `jeffrey` connects and issues the following query:

```
mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| @localhost     |
+----------------+
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

The `CURRENT_USER()` function is available as of MySQL 4.0.6. See Section 12.9.3, "Information Functions". Another thing you can do to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

5.6.6. Access Control, Stage 2: Request Verification

Once you establish a connection, the server enters Stage 2 of access control. For each request that comes in on the connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `db`, `host`, `tables_priv`, or `columns_priv` tables. (You may find it helpful to refer to Section 5.6.2, "How the Privilege System Works", which lists the columns present in each of the grant tables.)

The `user` table grants privileges that are assigned to you on a global basis and that apply no matter what the current database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host! In other words, `user` table privileges are superuser privileges. It is wise to grant privileges in the `user` table only to superusers such as database administrators. For other users, you should leave the privileges in the `user` table set to `'N'` and grant privileges at more specific levels only. You can grant privileges for particular databases, tables, or columns.

The `db` and `host` tables grant database-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters '%' and '_' can be used in the `Host` and `Db` columns of either table. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include '_' character as part of a database name, specify it as '_' in the `GRANT` statement.

- A '%' `Host` value in the `db` table means "any host." A blank `Host` value in the `db` table means "consult the `host` table for further information" (a process that is described later in this section).

- A '%' or blank `Host` value in the `host` table means "any host."

- A '%' or blank `Db` value in either table means "any database."

- A blank `User` value in either table matches the anonymous user.

The server reads in and sorts the `db` and `host` tables at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns, and sorts the `host` table based on the `Host` and `Db` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching entries, it uses the first match that it finds.

The `tables_priv` and `columns_priv` tables grant table-specific and column-specific privileges. Values in the scope columns of these tables can take the following form:

- The wildcard characters '%' and '_' can be used in the `Host` column of either table. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.

- A '%' or blank `Host` value in either table means "any host."

- The `Db`, `Table_name`, and `Column_name` columns cannot contain wildcards or be blank in either table.

The server sorts the `tables_priv` and `columns_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The request verification process is described here. (If you are familiar with the access-checking source code, you may notice that the description here differs slightly from the algorithm used in the code. The description is equivalent to what the code actually does; it differs only to make the explanation simpler.)

For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` table row because that is the only table that specifies administrative privileges. Access is granted if the row allows the requested operation and denied otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row doesn't grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` or `host` tables. (They contain no `Shutdown_priv` column, so there is no need to do so.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global (superuser) privileges by looking in the `user` table row. If the row allows the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges by checking the `db` and `host` tables:

1. The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user's hostname and MySQL username. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.

2. If there is a matching `db` table row and its `Host` column is not blank, that row defines the

user's database-specific privileges.

3. If the matching db table row's Host column is blank, it signifies that the host table enumerates which hosts should be allowed access to the database. In this case, a further lookup is done in the host table to find a match on the Host and Db columns. If no host table row matches, access is denied. If there is a match, the user's database-specific privileges are computed as the intersection (*not* the union!) of the privileges in the db and host table entries; that is, the privileges that are 'Y' in both entries. (This way you can grant general privileges in the db table row and then selectively restrict them on a host-by-host basis using the host table entries.)

After determining the database-specific privileges granted by the db and host table entries, the server adds them to the global privileges granted by the user table. If the result allows the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the tables_priv and columns_priv tables, adds those to the user's privileges, and allows or denies access based on the result.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
```

It may not be apparent why, if the global user row privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an INSERT INTO ... SELECT statement, you need both the INSERT and the SELECT privileges. Your privileges might be such that the user table row grants one privilege and the db table row grants the other. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either table by itself; the privileges granted by the entries in both tables must be combined.

The host table is not affected by the GRANT or REVOKE statements, so it is unused in most MySQL installations. If you modify it directly, you can use it for some specialized purposes, such as to maintain a list of secure servers. For example, at TcX, the host table contains a list of all machines on the local network. These are granted all privileges.

You can also use the host table to indicate hosts that are *not* secure. Suppose that you have a machine public.your.domain that is located in a public area that you do not consider secure. You can allow access to all hosts on your network except that machine by using host table entries like this:

```
+--------------------+----+-
| Host               | Db | ...
+--------------------+----+-
| public.your.domain | %  | ... (all privileges set to 'N')
| %.your.domain      | %  | ... (all privileges set to 'Y')
+--------------------+----+-
```

Naturally, you should always test your entries in the grant tables (for example, by using SHOW GRANTS or mysqlaccess) to make sure that your access privileges are actually set up the way you think they are.

5.6.7. When Privilege Changes Take Effect

When mysqld starts, all grant table contents are read into memory and become effective for access control at that point.

When the server reloads the grant tables, privileges for existing client connections are affected as

follows:

- Table and column privilege changes take effect with the client's next request.

- Database privilege changes take effect at the next USE *db_name* statement.

- Changes to global privileges and passwords take effect the next time the client connects.

If you modify the grant tables using GRANT, REVOKE, or SET PASSWORD, the server notices these changes and reloads the grant tables into memory again immediately.

If you modify the grant tables directly using statements such as INSERT, UPDATE, or DELETE, your changes have no effect on privilege checking until you either restart the server or tell it to reload the tables. To reload the grant tables manually, issue a FLUSH PRIVILEGES statement or execute a mysqladmin flush-privileges or mysqladmin reload command.

If you change the grant tables directly but forget to reload them, your changes have *no effect* until you restart the server. This may leave you wondering why your changes don't seem to make any difference!

5.6.8. Causes of `Access denied` Errors

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not running, you cannot connect to it. For example, if you attempt to connect to the server and see a message such as one of those following, one cause might be that the server is not running:

```
shell> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
shell> mysql
ERROR 2002: Can't connect to local MySQL server through socket
'/tmp/mysql.sock' (111)
```

  It might also be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from those on which the server is listening. To correct this when you invoke a client program, specify a --port option to indicate the proper port, or a --socket option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can do:

```
shell> netstat -ln | grep mysql
```

- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows on RPM distributions on Linux), the installation process initializes the mysql database containing the grant tables. For distributions that do not do this, you should initialize the grant tables manually by running the mysql_install_db script. For details, see Section 2.9.2, "Unix Post-Installation Procedures".

  One way to determine whether you need to initialize the grant tables is to look for a mysql directory under the data directory. (The data directory normally is named data or var and is located under your MySQL installation directory.) Make sure that you have a file named user.MYD in the mysql database directory. If you do not, execute the mysql_install_db script. After running this script and starting the server, test the initial privileges by executing this command:

```
shell> mysql -u root test
```

The server should let you connect without error.

- After a fresh installation, you should connect to the server and set up your users and their access permissions:

```
shell> mysql -u root mysql
```

The server should let you connect because the MySQL `root` user has no password initially. That is also a security risk, so setting the password for the `root` accounts is something you should do while you're setting up your other MySQL users. For instructions on setting the initial passwords, see Section 2.9.3, "Securing the Initial MySQL Accounts".

-

If you have updated an existing MySQL installation to a newer version, did you run the `mysql_fix_privilege_tables` script? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see Section 2.10.8, "Upgrading the Grant Tables".

- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

For information on how to deal with this, see Section 5.6.9, "Password Hashing in MySQL 4.1" and Section A.2.3, "`Client does not support authentication protocol`".

- If you try to connect as `root` and get the following error, it means that you don't have an row in the `user` table with a `User` column value of `'root'` and that `mysqld` cannot resolve the hostname for your client:

```
Access denied for user ''@'unknown' to database mysql
```

In this case, you must restart the server with the `--skip-grant-tables` option and edit your `/etc/hosts` or `\windows\hosts` file to add an entry for your host.

-

Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you don't specify them on the command line, check your environment and any applicable option files. For example, if you get `Access denied` when you run a client without any options, make sure that you haven't specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in Section 4.3.2, "Using Option Files". Environment variables are listed in Appendix G, *Environment Variables*.

- If you get the following error, it means that you are using an incorrect `root` password:

```
shell> mysqladmin -u root -pxxxx ver
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you haven't specified a password, it means that you

have an incorrect password listed in some option file. Try the `--no-defaults` option as described in the previous item.

For information on changing passwords, see Section 5.7.5, "Assigning Account Passwords".

If you have lost or forgotten the `root` password, you can restart `mysqld` with `--skip-grant-tables` to change the password. See Section A.4.1, "How to Reset the Root Password".

- If you change a password by using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must encrypt the password using the `PASSWORD()` function. If you do not use `PASSWORD()` for these statements, the password does not work. For example, the following statement sets a password, but fails to encrypt it, so the user is not able to connect afterward:

```
mysql> SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
```

Instead, set the password like this:

```
mysql> SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
```

The `PASSWORD()` function is unnecessary when you specify a password using the `GRANT` or (beginning with MySQL 5.0.2) `CREATE USER` statements, or the `mysqladmin password` command, all of which automatically use `PASSWORD()` to encrypt the password. See Section 5.7.5, "Assigning Account Passwords".

- `localhost` is a synonym for your local hostname, and is also the default host to which clients try to connect if you specify no host explicitly. However, connections to `localhost` on Unix systems do not work if you are using a MySQL version older than 3.23.27 that uses MIT-pthreads: `localhost` connections are made using Unix socket files, which were not supported by MIT-pthreads at that time.

To avoid this problem on such systems, you can use a `--host=127.0.0.1` option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` option that uses the actual hostname of the local host. In this case, the hostname must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

```
mysql> SELECT * FROM user;
```

The result should include an row with the `Host` and `User` columns matching your computer's hostname and your MySQL username.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether or not you were using a password. Normally, you should have one row in the `user` table that exactly matches the hostname and username that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without an password.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client hostname and username

that you are using when trying to connect.

If you do not know the IP number or hostname of the machine from which you are connecting, you should put a row with '%' as the Host column value in the user table. After trying to connect from the client machine, use a SELECT USER() query to see how you really did connect. (Then change the '%' in the user table row to the actual hostname that shows up in the log. Otherwise, your system is left insecure because it allows connections from any host for the given username.)

(Note that if you are running a version of MySQL older than 3.23.11, the output from USER() does not include the hostname. In this case, you must restart the server with the --log option, then obtain the hostname from the log.)

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the glibc library than the one you are using. In this case, you should either upgrade your operating system or glibc, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this isn't a big problem.

- If you specify a hostname when trying to connect, but get an error message where the hostname is not shown or is an IP number, it means that the MySQL server got an error when trying to resolve the IP number of the client host to a name:

```
shell> mysqladmin -u root -pxxxx -h some-hostname ver
Access denied for user 'root'@'' (using password: YES)
```

This indicates a DNS problem. To fix it, execute mysqladmin flush-hosts to reset the internal DNS hostname cache. See Section 7.5.6, "How MySQL Uses DNS".

Some permanent solutions are:

- Try to find out what is wrong with your DNS server and fix it.

- Specify IP numbers rather than hostnames in the MySQL grant tables.

- Put an entry for the client machine name in /etc/hosts.

- Start mysqld with the --skip-name-resolve option.

- Start mysqld with the --skip-host-cache option.

- On Unix, if you are running the server and the client on the same machine, connect to localhost. Unix connections to localhost use a Unix socket file rather than TCP/IP.

- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the hostname . (period). Connections to . use a named pipe rather than TCP/IP.

- If mysql -u root test works but mysql -h your_hostname -u root test results in Access denied (where your_hostname is the actual hostname of the local host), you may not have the correct name for your host in the user table. A common problem here is that the Host value in the user table row specifies an unqualified hostname, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have an entry with host 'tcx' in the user table, but your DNS tells MySQL that your hostname is 'tcx.subnet.se', the entry does not work. Try adding an entry to the user table that contains the IP number of your host as the Host column value. (Alternatively, you could add an entry to the user table with a Host value that contains a wildcard; for example, 'tcx.%'. However, use of hostnames ending with '%' is *insecure* and is *not* recommended!)

- If mysql -u user_name test works but mysql -u user_name other_db_name does not, you have not granted database access for other_db_name to the given user.

- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` doesn't work when executed on a remote client host, you have not enabled access to the server for the given username from the remote host.

- If you can't figure out why you get `Access denied`, remove from the `user` table all entries that have `Host` values containing wildcards (entries that contain '%' or '_'). A very common error is to insert a new entry with `Host='%'` and `User='some_user'`, thinking that this allows you to specify `localhost` to connect from the same machine. The reason that this doesn't work is that the default privileges include an entry with `Host='localhost'` and `User=''`. Because that entry has a `Host` value `'localhost'` that is more specific than `'%'`, it is used in preference to the new entry when connecting from `localhost`! The correct procedure is to insert a second entry with `Host='localhost'` and `User='some_user'`, or to delete the entry with `Host='localhost'` and `User=''`. After deleting the entry, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables.

- If you get the following error, you may have a problem with the `db` or `host` table:

```
Access to database denied
```

  If the entry selected from the `db` table has an empty value in the `Host` column, make sure that there are one or more corresponding entries in the `host` table specifying which hosts the `db` table entry applies to.

- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA INFILE` statement, your entry in the `user` table doesn't have the `FILE` privilege enabled.

- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to re-read the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` command, you won't need to specify the new password until after you flush the privileges, because the server won't know you've changed the password yet!

- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in Section 5.6.7, "When Privilege Changes Take Effect".

- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -pyour_pass db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=your_pass` syntax to specify the password. If you use the `-p` option alone, MySQL prompts you for the password.)

- For testing, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `mysqlaccess` script to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to start using the new grant tables. (Reloading the grant tables overrides the `--skip-grant-tables` option. This allows you to tell the server to begin using the grant tables again without stopping and restarting it.)

- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See Section F.1.2, "Creating Trace Files".

- If you have any other problems with the MySQL grant tables and feel you must post the problem to the mailing list, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. As always, post your problem using the `mysqlbug`

script. See Section 1.7.1.3, "How to Report Bugs or Problems". In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

5.6.9. Password Hashing in MySQL 4.1

MySQL user accounts are listed in the `user` table of the `mysql` database. Each MySQL account is assigned a password, although what is stored in the `Password` column of the `user` table is not the plaintext version of the password, but a hash value computed from it. Password hash values are computed by the `PASSWORD()` function.

MySQL uses passwords in two phases of client/server communication:

• When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account that the client wants to use.

• After the client connects, it can (if it has sufficient privileges) set or change the password hashes for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` function to generate a password hash, or by using the `GRANT` or `SET PASSWORD` statements.

In other words, the server *uses* hash values during authentication when a client first attempts to connect. The server *generates* hash values if a connected client invokes the `PASSWORD()` function or uses a `GRANT` or `SET PASSWORD` statement to set or change a password.

The password hashing mechanism was updated in MySQL 4.1 to provide better security and to reduce the risk of passwords being intercepted. However, this new mechanism is understood only by the 4.1 server and 4.1 clients, which can result in some compatibility problems. A 4.1 client can connect to a pre-4.1 server, because the client understands both the old and new password hashing mechanisms. However, a pre-4.1 client that attempts to connect to a 4.1 server may run into difficulties. For example, a 4.0 `mysql` client that attempts to connect to a 4.1 server may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

Another common example of this occurs when trying to use the older PHP **mysql** extension after upgrading to MySQL 4.1 or newer. (See Section 23.3.1, "Common Problems with MySQL and PHP".)

The following discussion describes the differences between the old and new password mechanisms, and what you should do if you upgrade your server to 4.1 but need to maintain backward compatibility with pre-4.1 clients. Additional information can be found in Section A.2.3, "Client does not support authentication protocol". This information is of particular importance to PHP programmers migrating MySQL databases from version 4.0 or lower to version 4.1 or higher.

Note: This discussion contrasts 4.1 behavior with pre-4.1 behavior, but the 4.1 behavior described here actually begins with 4.1.1. MySQL 4.1.0 is an "odd" release because it has a slightly different mechanism than that implemented in 4.1.1 and up. Differences between 4.1.0 and more recent versions are described further in Section 5.6.9.2, "Password Hashing in MySQL 4.1.0".

Prior to MySQL 4.1, password hashes computed by the `PASSWORD()` function are 16 bytes long. Such hashes look like this:

```
mysql> SELECT PASSWORD('mypass');
+--------------------+
| PASSWORD('mypass') |
+--------------------+
```

```
| 6f8c114b58f2ce9e   |
+--------------------+
```

The `Password` column of the `user` table (in which these hashes are stored) also is 16 bytes long before MySQL 4.1.

As of MySQL 4.1, the `PASSWORD()` function has been modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-------------------------------------------+
| PASSWORD('mypass')                        |
+-------------------------------------------+
| *43c8aa34cdc98eddd3de1fe9a9c2c2a9f92bb2098d75 |
+-------------------------------------------+
```

Accordingly, the `Password` column in the `user` table also must be 41 bytes long to store these values:

- If you perform a new installation of MySQL 4.1, the `Password` column is made 41 bytes long automatically.

- If you upgrade an older installation to 4.1, you should run the `mysql_fix_privilege_tables` script to increase the length of the `Password` column from 16 to 41 bytes. (The script does not change existing password values, which remain 16 bytes long.)

A widened `Password` column can store password hashes in both the old and new formats. The format of any given password hash value can be determined two ways:

- The obvious difference is the length (16 bytes versus 41 bytes).

- A second difference is that password hashes in the new format always begin with a '`*`' character, whereas passwords in the old format never do.

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.

- If the column is long, it can hold either short or long hashes, and the server can use either format:

  - Pre-4.1 clients can connect, although because they know only about the old hashing mechanism, they can authenticate only for accounts that have short hashes.

  - 4.1 clients can authenticate for accounts that have short or long hashes.

For short-hash accounts, the authentication process is actually a bit more secure for 4.1 clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating for account with short password hash

- 4.1 client authenticating for account with short password hash

- 4.1 client authenticating for account with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `--old-passwords` option. A 4.1 server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and the `--old-passwords` option must not be given. These conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using `PASSWORD()`, `GRANT`, or `SET PASSWORD`. This is the behavior that occurs if you have upgraded to 4.1 but have not yet run the `mysql_fix_privilege_tables` script to widen the `Password` column.

- If the `Password` column is wide, it can store either short or long password hashes. In this case, `PASSWORD()`, `GRANT`, and `SET PASSWORD` generate long hashes unless the server was started with the `--old-passwords` option. That option forces the server to generate short password hashes instead.

The purpose of the `--old-passwords` option is to allow you to maintain backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option doesn't affect authentication (4.1 clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that to occur, the account no longer could be used by pre-4.1 clients. Without the `--old-passwords` option, the following undesirable scenario is possible:

- An old client connects to an account that has a short password hash.

- The client changes its own password. Without `--old-passwords`, this results in the account having a long password hash.

- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the new hashing mechanism during authentication. (Once an account has a long password hash in the user table, only 4.1 clients can authenticate for it, because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is dangerous to run a 4.1 server without using the `--old-passwords` option. By running the server with `--old-passwords`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of the `--old-passwords` option is that any passwords you create or change use short hashes, even for 4.1 clients. Thus, you lose the additional security provided by long password hashes. If you want to create an account that has a long hash (for example, for use by 4.1 clients), you must do so while running the server without `--old-passwords`.

The following scenarios are possible for running a 4.1 server:

Scenario 1: Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.

- The server uses only short hashes during client authentication.

- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

- The `--old-passwords` option can be used but is superfluous because with a short `Password` column, the server generates only short password hashes anyway.

Scenario 2: Long `Password` column; server not started with `--old-passwords` option:

- Short or long hashes can be stored in the `Password` column.

- 4.1 clients can authenticate for accounts that have short or long hashes.

- Pre-4.1 clients can authenticate only for accounts that have short hashes.

- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made via `GRANT`, `PASSWORD()`, or `SET PASSWORD` results in the account being given a long password hash. From that point on, no pre-4.1 client can authenticate to that account until the client upgrades to 4.1.

To deal with this problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
mysql> SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` function instead:

```
mysql> SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');
```

`OLD_PASSWORD()` is useful for situations in which you explicitly want to generate a short hash.

Scenario 3: Long `Password` column; server started with `--old-passwords` option:

- Short or long hashes can be stored in the `Password` column.

- 4.1 clients can authenticate for accounts that have short or long hashes (but note that it is possible to create long hashes only when the server is started without `--old-passwords`).

- Pre-4.1 clients can authenticate only for accounts that have short hashes.

- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, you cannot create accounts that have long password hashes, because the `--old-passwords` option prevents generation of long hashes. Also, if you create an account with a long hash before using the `--old-passwords` option, changing the account's password while `--old-passwords` is in effect results in the account being given a short password, causing it to lose the security benefits of a longer hash.

The disadvantages for these scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using `OLD_PASSWORD()`.

In scenario 3, `--old-passwords` prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes, and you cannot change them back to long hashes while `--old-passwords` is in effect.

5.6.9.1. Implications of Password Hashing Changes for Application Programs

An upgrade to MySQL 4.1 can cause a compatibility issue for applications that use `PASSWORD()` to generate passwords for their own purposes. Applications really should not do this, because `PASSWORD()` should be used only to manage passwords for MySQL accounts. But some applications use `PASSWORD()` for their own purposes anyway.

If you upgrade to 4.1 and run the server under conditions where it generates long password hashes, an application that uses `PASSWORD()` for its own passwords breaks. The recommended course of action is to modify the application to use another function, such as `SHA1()` or `MD5()`, to produce hashed values. If that is not possible, you can use the `OLD_PASSWORD()` function, which is provided to generate short hashes in the old format. But note that `OLD_PASSWORD()` may one day no longer be supported.

If the server is running under circumstances where it generates short hashes, `OLD_PASSWORD()` is available but is equivalent to `PASSWORD()`.

PHP programmers migrating their MySQL databases from version 4.0 or lower to version 4.1 or higher should see Old Client.

5.6.9.2. Password Hashing in MySQL 4.1.0

Password hashing in MySQL 4.1.0 differs from hashing in 4.1.1 and up. The 4.1.0 differences are:

- Password hashes are 45 bytes long rather than 41 bytes.

- The `PASSWORD()` function is non-repeatable. That is, with a given argument *X*, successive calls to `PASSWORD(X)` generate different results.

These differences make authentication in 4.1.0 incompatible with that of releases that follow it. If you have upgraded to MySQL 4.1.0, it is recommended that you upgrade to a newer version as soon as possible. After you do, reassign any long passwords in the `user` table so that they are compatible with the 41-byte format.

5.7. MySQL User Account Management

This section describes how to set up accounts for clients of your MySQL server. It discusses the following topics:

- The meaning of account names and passwords as used in MySQL and how that compares to names and passwords used by your operating system

- How to set up new accounts and remove existing accounts

- How to change passwords

- Guidelines for using passwords securely

- How to use secure connections with SSL

5.7.1. MySQL Usernames and Passwords

A MySQL account is defined in terms of a username and the client host or hosts from which the user can connect to the server. The account also has a password. There are several distinctions between the way usernames and passwords are used by MySQL and the way they are used by your operating system:

- Usernames, as used by MySQL for authentication purposes, have nothing to do with usernames (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix username as the MySQL username, but that is for convenience only. The default can be overridden easily, because client programs allow any username to be specified with a `-u` or `--user` option. Because this means that anyone can attempt to connect to the server using any username, you can't make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a username for an account that has no password is able to connect successfully to the server.

- MySQL usernames can be up to 16 characters long. Operating system usernames might have a different maximum length. For example, Unix usernames typically are limited to eight characters.

- MySQL usernames can be up to 16 characters long. Changing the maximum length is not supported. If you still try to change it, for example by changing the length of the `User` column in the `mysql` database tables, this will likely result in strange and unpredictable effects. (Altering privilege tables isn't supported, anyway.) Operating system usernames might have a different maximum length. For example, Unix usernames typically are limited to eight characters.

- MySQL passwords have nothing to do with passwords for logging in to your operating system. There is no necessary connection between the password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

- MySQL encrypts passwords using its own algorithm. This encryption is different from that used during the Unix login process. MySQL password encryption is the same as that implemented by the `PASSWORD()` SQL function. Unix password encryption is the same as that implemented by the `ENCRYPT()` SQL function. See the descriptions of the `PASSWORD()` and `ENCRYPT()` functions in Section 12.9.2, "Encryption Functions". From version 4.1 on, MySQL employs a stronger authentication method that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the `mysql` database is captured. (In earlier versions, even though passwords are stored in encrypted form in the `user` table, knowledge of the encrypted password value could be used to connect to the MySQL server.)

When you install MySQL, the grant tables are populated with an initial set of accounts. These accounts have names and access privileges that are described in Section 2.9.3, "Securing the Initial MySQL Accounts", which also discusses how to assign passwords to them. Thereafter, you normally set up, modify, and remove MySQL accounts using the `GRANT` and `REVOKE` statements. See Section 13.5.1.3, "`GRANT` and `REVOKE` Syntax".

When you connect to a MySQL server with a command-line client, you should specify the username and password for the account that you want to use:

```
shell> mysql --user=monty --password=guess db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u monty -pguess db_name
```

There must be *no space* between the `-p` option and the following password value. See Section 5.6.4, "Connecting to the MySQL Server".

The preceding commands include the password value on the command line, which can be a security risk. See Section 5.7.6, "Keeping Your Password Secure". To avoid this, specify the `--password` or `-p` option without any following password value:

```
shell> mysql --user=monty --password db_name
shell> mysql -u monty -p db_name
```

Then the client program prints a prompt and waits for you to enter the password. (In these examples, *db_name* is *not* interpreted as a password, because it is separated from the preceding password option by a space.)

On some systems, the library call that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL doesn't have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

5.7.2. Adding New User Accounts to MySQL

You can create MySQL accounts in two ways:

* By using `GRANT` statements

* By manipulating the MySQL grant tables directly

The preferred method is to use `GRANT` statements, because they are more concise and less error-prone. `GRANT` is available as of MySQL 3.22.11; its syntax is described in Section 13.5.1.3, "`GRANT` and `REVOKE` Syntax".

Another option for creating accounts is to use one of several available third-party programs that offer capabilities for MySQL account administration. `phpMyAdmin` is one such program.

The following examples show how to use the `mysql` client program to set up new users. These examples assume that privileges are set up according to the defaults described in Section 2.9.3, "Securing the Initial MySQL Accounts". This means that to make changes, you must connect to the MySQL server as the MySQL `root` user, and the `root` account must have the `INSERT` privilege for the `mysql` database and the `RELOAD` administrative privilege.

First, use the `mysql` program to connect to the server as the MySQL `root` user:

```
shell> mysql --user=root mysql
```

If you have assigned a password to the `root` account, you'll also need to supply a `--password` or `-p` option for this `mysql` command and also for those later in this section.

After connecting to the server as `root`, you can add new accounts. The following statements use `GRANT` to set up four new accounts:

```
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'localhost'
    ->     IDENTIFIED BY 'some_pass' WITH GRANT OPTION;
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'%'
    ->     IDENTIFIED BY 'some_pass' WITH GRANT OPTION;
mysql> GRANT RELOAD,PROCESS ON *.* TO 'admin'@'localhost';
mysql> GRANT USAGE ON *.* TO 'dummy'@'localhost';
```

The accounts created by these `GRANT` statements have the following properties:

- Two of the accounts have a username of `monty` and a password of `some_pass`. Both accounts are superuser accounts with full privileges to do anything. One account (`'monty'@'localhost'`) can be used only when connecting from the local host. The other (`'monty'@'%'`) can be used to connect from any other host. Note that it is necessary to have both accounts for `monty` to be able to connect from anywhere as `monty`. Without the `localhost` account, the anonymous-user account for `localhost` that is created by `mysql_install_db` would take precedence when `monty` connects from the local host. As a result, `monty` would be treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the `'monty'@'%'` account and thus comes earlier in the `user` table sort order. (`user` table sorting is discussed in Section 5.6.5, "Access Control, Stage 1: Connection Verification".)

- One account has a username of `admin` and no password. This account can be used only by connecting from the local host. It is granted the `RELOAD` and `PROCESS` administrative privileges. These privileges allow the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist` . No privileges are granted for accessing any databases. You could add such privileges later by issuing additional `GRANT` statements.

- One account has a username of `dummy` and no password. This account can be used only by connecting from the local host. No privileges are granted. The `USAGE` privilege in the `GRANT` statement allows you to create an account without giving it any privileges. It has the effect of setting all the global privileges to `'N'`. It is assumed that you will grant specific privileges to the account later.

As an alternative to `GRANT`, you can create the same accounts directly by issuing `INSERT` statements and then telling the server to reload the grant tables:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user
    ->     VALUES('localhost','monty',PASSWORD('some_pass'),
    ->     'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user
    ->     VALUES('%','monty',PASSWORD('some_pass'),
    ->     'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user SET Host='localhost',User='admin',
    ->     Reload_priv='Y', Process_priv='Y';
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('localhost','dummy','');
mysql> FLUSH PRIVILEGES;
```

The reason for using `FLUSH PRIVILEGES` when you create accounts with `INSERT` is to tell the server to re-read the grant tables. Otherwise, the changes go unnoticed until you restart the server. With `GRANT`, `FLUSH PRIVILEGES` is unnecessary.

The reason for using the `PASSWORD()` function with `INSERT` is to encrypt the password. The `GRANT` statement encrypts the password for you, so `PASSWORD()` is unnecessary.

The `'Y'` values enable privileges for the accounts. Depending on your MySQL version, you may have to use a different number of `'Y'` values in the first two `INSERT` statements. (Versions prior to 3.22.11 have fewer privilege columns, and versions from 4.0.2 on have more.) For the `admin` account, the more readable extended `INSERT` syntax using `SET` that is available starting with MySQL 3.22.11 is used.

In the `INSERT` statement for the `dummy` account, only the `Host`, `User`, and `Password` columns in the `user` table record are assigned values. None of the privilege columns are set explicitly, so MySQL assigns them all the default value of `'N'`. This is equivalent to what `GRANT USAGE` does.

Note that to set up a superuser account, it is necessary only to create a `user` table entry with the privilege columns set to `'Y'`. `user` table privileges are global, so no entries in any of the other grant tables are needed.

The next examples create three accounts and give them access to specific databases. Each of them has a username of `custom` and password of `obscure`.

To create the accounts with `GRANT`, use the following statements:

```
shell> mysql --user=root mysql
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ->     ON bankaccount.*
    ->     TO 'custom'@'localhost'
    ->     IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ->     ON expenses.*
    ->     TO 'custom'@'whitehouse.gov'
    ->     IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ->     ON customer.*
    ->     TO 'custom'@'server.domain'
    ->     IDENTIFIED BY 'obscure';
```

The three accounts can be used as follows:

- The first account can access the `bankaccount` database, but only from the local host.

- The second account can access the `expenses` database, but only from the host `white-house.gov`.

- The third account can access the `customer` database, but only from the host `server.domain`.

To set up the `custom` accounts without `GRANT`, use `INSERT` statements as follows to modify the grant tables directly:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('localhost','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('whitehouse.gov','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('server.domain','custom',PASSWORD('obscure'));
mysql> INSERT INTO db
    ->     (Host,Db,User,Select_priv,Insert_priv,
    ->     Update_priv,Delete_priv,Create_priv,Drop_priv)
    ->     VALUES('localhost','bankaccount','custom',
    ->     'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
    ->     (Host,Db,User,Select_priv,Insert_priv,
    ->     Update_priv,Delete_priv,Create_priv,Drop_priv)
    ->     VALUES('whitehouse.gov','expenses','custom',
    ->     'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
    ->     (Host,Db,User,Select_priv,Insert_priv,
    ->     Update_priv,Delete_priv,Create_priv,Drop_priv)
    ->     VALUES('server.domain','customer','custom',
    ->     'Y','Y','Y','Y','Y','Y');
mysql> FLUSH PRIVILEGES;
```

The first three `INSERT` statements add `user` table entries that allow the user `custom` to connect from the various hosts with the given password, but grant no global privileges (all privileges are set to the default value of `'N'`). The next three `INSERT` statements add `db` table entries that grant privileges to `custom` for the `bankaccount`, `expenses`, and `customer` databases, but only when accessed from the proper hosts. As usual when you modify the grant tables directly, you tell the server to reload them with `FLUSH PRIVILEGES` so that the privilege changes take effect.

If you want to give a specific user access from all machines in a given domain (for example, `mydomain.com`), you can issue a `GRANT` statement that uses the '`%`' wildcard character in the host part of the account name:

```
mysql> GRANT ...
    ->       ON *.*
    ->       TO 'myname'@'%.mydomain.com'
    ->       IDENTIFIED BY 'mypass';
```

To do the same thing by modifying the grant tables directly, do this:

```
mysql> INSERT INTO user (Host,User,Password,...)
    ->       VALUES('%.mydomain.com','myname',PASSWORD('mypass'),...);
mysql> FLUSH PRIVILEGES;
```

5.7.3. Removing User Accounts from MySQL

To remove an account, use the `DROP USER` statement, which was added in MySQL 4.1.1. For older versions of MySQL, use `DELETE` instead. The account removal procedure is described in Section 13.5.1.2, "`DROP USER` Syntax".

5.7.4. Limiting Account Resources

Before MySQL 4.0.2, the only available method for limiting use of MySQL server resources is to set the `max_user_connections` system variable to a non-zero value. But that method is strictly global. It does not allow for management of individual accounts. Also, it limits only the number of simultaneous connections made using a single account, not what a client can do once connected. Both types of control are interest to many MySQL administrators, particularly those for Internet Service Providers.

Starting from MySQL 4.0.2, you can limit the following server resources for individual accounts:

*   The number of queries that an account can issue per hour

*   The number of updates that an account can issue per hour

*   The number of times an account can connect to the server per hour

Any statement that a client can issue counts against the query limit. Only statements that modify databases or tables count against the update limit.

From MySQL 5.0.3 on, it is also possible to limit the number of simultaneous connections to the server on a per-account basis.

An account in this context is a single record in the `user` table. Each account is uniquely identified by its `User` and `Host` column values.

As a prerequisite for using this feature, the `user` table in the `mysql` database must contain the resource-related columns. Resource limits are stored in the `max_questions`, `max_updates`, `max_connections`, and `max_user_connections` columns. If your `user` table doesn't have these columns, it must be upgraded; see Section 2.10.8, "Upgrading the Grant Tables".

To set resource limits with a `GRANT` statement, use a `WITH` clause that names each resource to be limited and a per-hour count indicating the limit value. For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue this statement:

```
mysql> GRANT ALL ON customer.* TO 'francis'@'localhost'
    ->       IDENTIFIED BY 'frank'
    ->       WITH MAX_QUERIES_PER_HOUR 20
```

```
      ->              MAX_UPDATES_PER_HOUR 10
      ->              MAX_CONNECTIONS_PER_HOUR 5
      ->              MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the WITH clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. If the GRANT statement has no WITH clause, the limits are each set to the default value of zero (that is, no limit). For MAX_USER_CONNECTIONS, the limit is an integer indicating the maximum number of simultaneous connections the account can make at any one time. If the limit is set to the default value of zero, the max_user_connections system variable determines the number of simultaneous connections for the account.

To set or change limits for an existing account, use a GRANT USAGE statement at the global level (ON *.*). The following statement changes the query limit for francis to 100:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
    ->        WITH MAX_QUERIES_PER_HOUR 100;
```

This statement leaves the account's existing privileges unchanged and modifies only the limit values specified.

To remove an existing limit, set its value to zero. For example, to remove the limit on how many times per hour francis can connect, use this statement:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
    ->        WITH MAX_CONNECTIONS_PER_HOUR 0;
```

Resource-use counting takes place when any account has a non-zero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, further connections for the account are rejected until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, further queries or updates are rejected until the hour is up. In all such cases, an appropriate error message is issued.

Resource counting is done per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

• To reset the current counts to zero for all accounts, issue a FLUSH USER_RESOURCES statement. The counts also can be reset by reloading the grant tables (for example, with a FLUSH PRIVILEGES statement or a mysqladmin reload command).

• The counts for an individual account can be set to zero by re-granting it any of its limits. To do this, use GRANT USAGE as described earlier and specify a limit value equal to the value that the account currently has.

Counter resets do not affect the MAX_USER_CONNECTIONS limit.

All counts begin at zero when the server starts; counts are not carried over through a restart.

5.7.5. Assigning Account Passwords

Passwords may be assigned from the command line by using the mysqladmin command:

```
shell> mysqladmin -u user_name -h host_name password "newpwd"
```

The account for which this command resets the password is the one with a `user` table record that matches *user_name* in the `User` column and the client host *from which you connect* in the `Host` column.

Another way to assign a password to an account is to issue a `SET PASSWORD` statement:

```
mysql> SET PASSWORD FOR 'jeffrey'@'%' = PASSWORD('biscuit');
```

Only users such as `root` with update access to the `mysql` database can change the password for other users. If you are not connected as an anonymous user, you can change your own password by omitting the `FOR` clause:

```
mysql> SET PASSWORD = PASSWORD('biscuit');
```

You can also use a `GRANT USAGE` statement at the global level (`ON *.*`) to assign a password to an account without affecting the account's current privileges:

```
mysql> GRANT USAGE ON *.* TO 'jeffrey'@'%' IDENTIFIED BY 'biscuit';
```

Although it is generally preferable to assign passwords using one of the preceding methods, you can also do so by modifying the `user` table directly:

- To establish a password when creating a new account, provide a value for the `Password` column:

```
shell> mysql -u root mysql
mysql> INSERT INTO user (Host,User,Password)
    -> VALUES('%','jeffrey',PASSWORD('biscuit'));
mysql> FLUSH PRIVILEGES;
```

- To change the password for an existing account, use `UPDATE` to set the `Password` column value:

```
shell> mysql -u root mysql
mysql> UPDATE user SET Password = PASSWORD('bagel')
    -> WHERE Host = '%' AND User = 'francis';
mysql> FLUSH PRIVILEGES;
```

When you assign an account a password using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must use the `PASSWORD()` function to encrypt it. (The only exception is that you need not use `PASSWORD()` if the password is empty.) `PASSWORD()` is necessary because the `user` table stores passwords in encrypted form, not as plaintext. If you forget that fact, you are likely to set passwords like this:

```
shell> mysql -u root mysql
mysql> INSERT INTO user (Host,User,Password)
    -> VALUES('%','jeffrey','biscuit');
mysql> FLUSH PRIVILEGES;
```

The result is that the literal value `'biscuit'` is stored as the password in the `user` table, not the encrypted value. When `jeffrey` attempts to connect to the server using this password, the value is encrypted and compared to the value stored in the `user` table. However, the stored value is the literal string `'biscuit'`, so the comparison fails and the server rejects the connection:

```
shell> mysql -u jeffrey -pbiscuit test
Access denied
```

If you set passwords using the `GRANT ... IDENTIFIED BY` statement or the `mysqladmin password` command, they both take care of encrypting the password for you. The `PASSWORD()` function is unnecessary.

Note: `PASSWORD()` encryption is different from Unix password encryption. See Section 5.7.1, "MySQL Usernames and Passwords".

5.7.6. Keeping Your Password Secure

On an administrative level, you should never grant access to the `mysql.user` table to any non-administrative accounts. Passwords in the `user` table are stored in encrypted form, but in versions of MySQL earlier than 4.1, knowing the encrypted password for an account makes it possible to connect to the server using that account.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method:

- Use a `-p`*your_pass* or `--password=`*your_pass* option on the command line. For example:

  ```
  shell> mysql -u francis -pfrank db_name
  ```

  This is convenient but insecure, because your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence, but there is still a brief interval during which the value is visible.

- Use a `-p` or `--password` option with no password value specified. In this case, the client program solicits the password from the terminal:

  ```
  shell> mysql -u francis -p db_name
  Enter password: ********
  ```

  The '`*`' characters indicate where you enter your password. The password is not displayed as you enter it.

  It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs non-interactively, there is no opportunity to enter the password from the terminal. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password!

- Store your password in an option file. For example, on Unix you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

  ```
  [client]
  password=your_pass
  ```

  If you store your password in `.my.cnf`, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

  ```
  shell> chmod 600 .my.cnf
  ```

  Section 4.3.2, "Using Option Files" discusses option files in more detail.

- Store your password in the `MYSQL_PWD` environment variable. This method of specifying your

MySQL password must be considered extremely insecure and should not be used. Some versions of `ps` include an option to display the environment of running processes. If you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments. See Appendix G, *Environment Variables*.

All in all, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

5.7.7. Using Secure Connections

Beginning with version 4.0.0, MySQL has support for secure (encrypted) connections between MySQL clients and the server using the Secure Sockets Layer (SSL) protocol. This section discusses how to use SSL connections.

Beginning with version 5.0.10, MySQL has built-in yaSSL support. yaSSL is an SSL Library for programmers building security functionality into their applications and devices. yaSSL employs the dual licensing model, like MySQL, so it is available under GPL and commercial licenses. More information about yaSSL can be found on http://yassl.com.

Using MySQL's built-in yaSSL support makes it easier to use secure connections. You don't have to install OpenSSL and perform the other steps described in Section 5.7.7.2, "Requirements (OpenSSL)". Apart from that, most of the information given in this section applies to OpenSSL as well as to yaSSL.

The standard configuration of MySQL is intended to be as fast as possible, so encrypted connections are not used by default. Doing so would make the client/server protocol much slower. Encrypting data is a CPU-intensive operation that requires the computer to do additional work and can delay other MySQL tasks. For applications that require the security provided by encrypted connections, the extra computation is warranted.

MySQL allows encryption to be enabled on a per-connection basis. You can choose a normal unencrypted connection or a secure encrypted SSL connection according the requirements of individual applications.

5.7.7.1. Basic SSL Concepts

To understand how MySQL uses SSL, it's necessary to explain some basic SSL and X509 concepts. People who are familiar with them can skip this part.

By default, MySQL uses unencrypted connections between the client and the server. This means that someone with access to the network could watch all your traffic and look at the data being sent or received. They could even change the data while it is in transit between client and server. To improve security a little, you can compress client/server traffic by using the `--compress` option when invoking client programs. However, this does not foil a determined attacker.

When you need to move information over a network in a secure fashion, an unencrypted connection is unacceptable. Encryption is the way to make any kind of data unreadable. In fact, today's practice requires many additional security elements from encryption algorithms. They should resist many kind of known attacks such as changing the order of encrypted messages or replaying data twice.

SSL is a protocol that uses different encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect any data change, loss, or replay. SSL also incorporates algorithms that provide identity verification using the X509 standard.

X509 makes it possible to identify someone on the Internet. It is most commonly used in e-commerce applications. In basic terms, there should be some company called a "Certificate Authority" (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can show the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data encrypted with this public key can be decrypted only using the

corresponding secret key, which is held by the owner of the certificate.

If you need more information about SSL, X509, or encryption, use your favorite Internet search engine to search for keywords in which you are interested.

5.7.7.2. Requirements (OpenSSL)

To use SSL connections between the MySQL server and client programs, your system must be able to support OpenSSL and your version of MySQL must be 4.0.0 or newer. If you're using a MySQL version with built-in yaSSL support (as of version 5.0.10), don't read this section, but rather Section 5.7.7.3, "Using yaSSL".

To get secure connections to work with MySQL, you must do the following:

1. Install the OpenSSL library. We have tested MySQL with OpenSSL 0.9.6. If you need OpenSSL, visit http://www.openssl.org.

2. When you configure MySQL, run the `configure` script with the `--with-vio` and `--with-openssl` options.

3. Make sure that you have upgraded your grant tables to include the SSL-related columns in the `mysql.user` table. This is necessary if your grant tables date from a version prior to MySQL 4.0.0. The upgrade procedure is described in Section 2.10.8, "Upgrading the Grant Tables".

4. To check whether a running `mysqld` server supports OpenSSL, examine the value of the `have_openssl` system variable:

   ```
   mysql> SHOW VARIABLES LIKE 'have_openssl';
   +---------------+-------+
   | Variable_name | Value |
   +---------------+-------+
   | have_openssl  | YES   |
   +---------------+-------+
   ```

   If the value is `YES`, the server supports OpenSSL connections.

5.7.7.3. Using yaSSL

Using MySQL's built-in yaSSL support makes it easier to use secure connections. You don't have to install OpenSSL and perform the other steps described in Section 5.7.7.2, "Requirements (OpenSSL)". Also, both MySQL and yaSSL employ the same licensing model.

Currently, yaSSL support is available for these platforms:

- Linux/x86-64 Red Hat Enterprise 3.0

- Linux RHAS21 Itanium-2 with gcc, statically linked

- Linux Itanium-2 with gcc

- Windows (all builds)

If you want to enable yaSSL when building MySQL from source, you should configure MySQL like this:

```
./configure --with-yassl=yes
```

To start the MySQL server with yaSSL support, use the same options as with OpenSSL support and

identify the certificates needed to establish a secure connection:

```
shell> mysqld --ssl-ca=cacert.pem \
       --ssl-cert=server-cert.pem \
       --ssl-key=server-key.pem
```

- `--ssl-ca` identifies the Certificate Authority certificate.

- `--ssl-cert` identifies the server certificate.

- `--ssl-key` identifies the client certificate.

To establish a secure connection to a MySQL server with yaSSL support, start a client like this:

```
shell> mysql --ssl-ca=cacert.pem \
       --ssl-cert=server-cert.pem \
       --ssl-key=server-key.pem
```

In other words, the options are the same as for the server, and the Certificate Authority certificate has to be the same.

To establish a secure connection from an application program, use the `mysql_ssl_set()` API function to set the appropriate certificate options, before calling `mysql_real_connect()`. See Section 23.2.3.58, "`mysql_ssl_set()`".

5.7.7.4. Setting Up SSL Certificates for MySQL

Here is an example for setting up SSL certificates for MySQL:

```
DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
# directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
# Generation of Certificate Authority(CA)

# Create a my.cnf file that you can use to test the certificates
#

cnf=""
cnf="$cnf [client]"
cnf="$cnf ssl-ca=$DIR/cacert.pem"
cnf="$cnf ssl-cert=$DIR/client-cert.pem"
cnf="$cnf ssl-key=$DIR/client-key.pem"
cnf="$cnf [mysqld]"
cnf="$cnf ssl-ca=$DIR/cacert.pem"
cnf="$cnf ssl-cert=$DIR/server-cert.pem"
cnf="$cnf ssl-key=$DIR/server-key.pem"
echo $cnf | replace " " '
' > $DIR/my.cnf
```

To test SSL connections, start the server as follows, where `$DIR` is the pathname to the directory where the sample `my.cnf` option file is located:

```
shell> mysqld --defaults-file=$DIR/my.cnf &
```

Then invoke a client program using the same option file:

```
shell> mysql --defaults-file=$DIR/my.cnf
```

If you have a MySQL source distribution, you can also test your setup by modifying the preceding `my.cnf` file to refer to the demonstration certificate and key files in the `SSL` directory of the distribution.

5.7.7.5. SSL `GRANT` Options

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the username and password. To specify SSL-related options for a MySQL account, use the `RE-QUIRE` clause of the `GRANT` statement. See Section 13.5.1.3, "`GRANT` and `REVOKE` Syntax".

There are different possibilities for limiting connection types for an account:

- If an account has no SSL or X509 requirements, unencrypted connections are allowed if the username and password are valid. However, encrypted connections also can be used at the client's option, if the client has the proper certificate and key files.

- `REQUIRE SSL` option limits the server to allow only SSL encrypted connections for the account. Note that this option can be omitted if there are any ACL records that allow non-SSL connections.

```
mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    -> IDENTIFIED BY 'goodsecret' REQUIRE SSL;
```

- `REQUIRE X509` means that the client must have a valid certificate but that the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates.

```
mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    -> IDENTIFIED BY 'goodsecret' REQUIRE X509;
```

- `REQUIRE ISSUER 'issuer'` places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA `'issuer'`. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary.

```
mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    -> IDENTIFIED BY 'goodsecret'
    -> REQUIRE ISSUER '/C=FI/ST=Some-State/L=Helsinki/
       O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the `ISSUER` value should be entered as a single string.

- `REQUIRE SUBJECT 'subject'` places the restriction on connection attempts that the client must present a valid X509 certificate with subject `'subject'` on it. If the client presents a certificate that is valid but has a different subject, the server rejects the connection.

```
mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    -> IDENTIFIED BY 'goodsecret'
    -> REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
       O=MySQL demo client certificate/
       CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the `SUBJECT` value should be entered as a single string.

- `REQUIRE CIPHER 'cipher'` is needed to ensure that strong enough ciphers and key lengths are used. SSL itself can be weak if old algorithms with short encryption keys are used. Using this option, we can ask for some exact cipher method to allow a connection.

```
mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    -> IDENTIFIED BY 'goodsecret'
    -> REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause like this:

```
mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    -> IDENTIFIED BY 'goodsecret'
    -> REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
       O=MySQL demo client certificate/
       CN=Tonu Samuel/Email=tonu@example.com'
    -> AND ISSUER '/C=FI/ST=Some-State/L=Helsinki/
       O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com'
    -> AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

Note that the `SUBJECT` and `ISSUER` values each should be entered as a single string.

Starting from MySQL 4.0.4, the `AND` keyword is optional between `REQUIRE` options.

The order of the options does not matter, but no option can be specified twice.

5.7.7.6. SSL Command-Line Options

The following list describes options that are used for specifying the use of SSL, certificate files, and key files. These options are available beginning with MySQL 4.0. They may be given on the command line or in an option file.

- `--ssl`

For the server, this option specifies that the server allows SSL connections. For a client program, it allows the client to connect to the server using SSL. This option is not sufficient in itself to cause an SSL connection to be used. You must also specify the `--ssl-ca`, `--ssl-cert`, and

`--ssl-key` options.

This option is more often used in its opposite form to indicate that SSL should *not* be used. To do this, specify the option as `--skip-ssl` or `--ssl=0`.

Note that use of `--ssl` doesn't *require* an SSL connection. For example, if the server or client is compiled without SSL support, a normal unencrypted connection is used.

The secure way to ensure that an SSL connection is used is to create an account on the server that includes a `REQUIRE SSL` clause in the `GRANT` statement. Then use this account to connect to the server, with both a server and client that have SSL support enabled.

- `--ssl-ca=file_name`

  The path to a file with a list of trusted SSL CAs.

- `--ssl-capath=directory_name`

  The path to a directory that contains trusted SSL CA certificates in pem format.

- `--ssl-cert=file_name`

  The name of the SSL certificate file to use for establishing a secure connection.

- `--ssl-cipher=cipher_list`

  A list of allowable ciphers to use for SSL encryption. `cipher_list` has the same format as the `openssl ciphers` command.

  Example: `--ssl-cipher=ALL:-AES:-EXP`

- `--ssl-key=file_name`

  The name of the SSL key file to use for establishing a secure connection.

5.7.7.7. Connecting to MySQL Remotely from Windows with SSH

Here is a note about how to connect to get a secure connection to remote MySQL server with SSH (by David Carlson <dcarlson@mplcomm.com>):

1. Install an SSH client on your Windows machine. As a user, the best non-free one I've found is from `SecureCRT` from http://www.vandyke.com/. Another option is `f-secure` from http://www.f-secure.com/. You can also find some free ones on `Google` at http://directory.google.com/Top/Computers/Security/Products_and_Tools/Cryptography/SSH/Clients/Windows/.

2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value may not be the same as the username of your MySQL account.

3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306`, `remote_host: yourmysqlservername_or_ip`, `remote_port: 3306`) or a local forward (Set `port: 3306`, `host: localhost`, `remote port: 3306`).

4. Save everything, otherwise you'll have to redo it the next time.

5. Log in to your server with the SSH session you just created.

6. On your Windows machine, start some ODBC application (such as Access).

7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not

yourmysqlservername.

You should have an ODBC connection to MySQL, encrypted using SSH.

5.8. Backup and Recovery

This section discusses how to make database backups (full and incremental) and how to perform table maintenance. The syntax of the SQL statements described here is given in Section 13.5, "Database Administration Statements". Much of the information here pertains primarily to `MyISAM` tables. `InnoDB` backup procedures are given in Section 15.9, "Backing Up and Recovering an InnoDB Database".

5.8.1. Database Backups

Because MySQL tables are stored as files, it is easy to do a backup. To get a consistent backup, do a `LOCK TABLES` on the relevant tables, followed by `FLUSH TABLES` for the tables. See Section 13.4.5, "`LOCK TABLES` and `UNLOCK TABLES` Syntax" and Section 13.5.5.2, "`FLUSH` Syntax". You need only a read lock; this allows other clients to continue to query the tables while you are making a copy of the files in the database directory. The `FLUSH TABLES` statement is needed to ensure that the all active index pages are written to disk before you start the backup.

If you want to make an SQL-level backup of a table, you can use `SELECT INTO ... OUTFILE` or `BACKUP TABLE`. For `SELECT INTO ... OUTFILE`, the output file cannot previously exist. For `BACKUP TABLE`, the same is true as of MySQL 3.23.56 and 4.0.12, because this would be a security risk. See Section 13.2.7, "`SELECT` Syntax" and Section 13.5.2.2, "`BACKUP TABLE` Syntax".

Another way to back up a database is to use the `mysqldump` program or the `mysqlhotcopy script`. See Section 8.8, "mysqldump — A Database Backup Program" and Section 8.9, "mysqlhotcopy — A Database Backup Program".

1. Do a full backup of your database:

   ```
   shell> mysqldump --tab=/path/to/some/dir --opt db_name
   ```

   Or:

   ```
   shell> mysqlhotcopy db_name /path/to/some/dir
   ```

   You can also simply copy all table files (`*.frm`, `*.MYD`, and `*.MYI` files) as long as the server isn't updating anything. The `mysqlhotcopy` script uses this method. (But note that these methods do not work if your database contains `InnoDB` tables. `InnoDB` does not store table contents in database directories, and `mysqlhotcopy` works only for `MyISAM` and `ISAM` tables.)

2.
   Stop `mysqld` if it's running, then start it with the `--log-bin[=file_name]` option. See Section 5.10.4, "The Binary Log". The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you executed `mysqldump`.

For `InnoDB` tables, it's possible to perform an online backup that takes no locks on tables; see Section 8.8, "mysqldump — A Database Backup Program"

MySQL supports incremental backups: You need to start the server with the `--log-bin` option to enable binary logging; see Section 5.10.4, "The Binary Log". At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup),

you should rotate the binary log by using FLUSH LOGS. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained further below. The next time you do a full backup, you should also rotate the binary log using FLUSH LOGS, mysqldump --flush-logs, or mysqlhotcopy --flushlogs. See Section 8.8, "mysqldump — A Database Backup Program" and Section 8.9, "mysqlhotcopy — A Database Backup Program".

If your MySQL server is a slave replication server, then regardless of the backup method you choose, you should also back up the master.info and relay-log.info files when you back up your slave's data. These files are always needed to resume replication after you restore the slave's data. If your slave is subject to replicating LOAD DATA INFILE commands, you should also back up any SQL_LOAD-* files that may exist in the directory specified by the --slave-load-tmpdir option. (This location defaults to the value of the tmpdir variable if not specified.) The slave needs these files to resume replication of any interrupted LOAD DATA INFILE operations.

If you have to restore MyISAM tables, try to recover them using REPAIR TABLE or myisamchk -r first. That should work in 99.9% of all cases. If myisamchk fails, try the following procedure. Note that it works only if you have enabled binary logging by starting MySQL with the --log-bin option; see Section 5.10.4, "The Binary Log".

1. Restore the original mysqldump backup, or binary backup.

2. Execute the following command to re-run the updates in the binary logs:

   ```
   shell> mysqlbinlog hostname-bin.[0-9]* | mysql
   ```

   In your case, you may want to re-run only certain binary logs, from certain positions (usually you want to re-run all binary logs from the date of the restored backup, excepting possibly some incorrect queries). See Section 8.5, "mysqlbinlog — Utility for Processing Binary Log Files" for more information on the mysqlbinlog utility and how to use it.

   If you are using the update logs instead (which is a deprecated feature removed in MySQL 5.0), you can process their contents like this:

   ```
   shell> ls -1 -t -r hostname.[0-9]* | xargs cat | mysql
   ```

   ls is used to sort the update log filenames into the right order.

You can also do selective backups of individual files:

- To dump the table, use SELECT * INTO OUTFILE 'file_name' FROM tbl_name.

- To reload the table, use and restore with LOAD DATA INFILE 'file_name' REPLACE ... To avoid duplicate records, the table must have a PRIMARY KEY or a UNIQUE index. The REPLACE keyword causes old records to be replaced with new ones when a new record duplicates an old record on a unique key value.

If you have performance problems with your server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See Section 6.1, "Introduction to Replication".

If you are using a Veritas filesystem, you can make a backup like this:

1. From a client program, execute FLUSH TABLES WITH READ LOCK.

2. From another shell, execute mount vxfs snapshot.

3. From the first client, execute `UNLOCK TABLES`.

4. Copy files from the snapshot.

5. Unmount the snapshot.

5.8.2. Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that allows you to recover data after several types of crashes:

- Operating system crash

- Power failure

- Filesystem crash

- Hardware problem (hard drive, motherboard, and so forth)

The following instructions assume a minimum version of MySQL 4.1.8, because some `mysqldump` options used here are not available in earlier versions.

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` programs. You should include such options as necessary so that the MySQL server allows you to connect to it.

We'll assume that data is stored into the `InnoDB` storage engine of MySQL, which has support for transactions and automatic crash recovery. We'll always assume that the MySQL server is under load at the time of crash. If it were not, no recovery would ever be needed.

For the cases of operating system crashes or power failures, we can assume the MySQL disk data is available after a restart. The `InnoDB` data files might not contain consistent data due to the crash, but `InnoDB` reads its logs and finds in them the list of pending committed and non-committed transactions that have not been flushed to the data files. `InnoDB` automatically rolls back those that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of filesystem crashes or hardware problems, we can assume that the MySQL disk data

is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it's necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it's necessary to recover our MySQL data from backups, which means that we must already have made backups. To make sure that is the case, let's step back in time and design a backup policy.

5.8.2.1. Backup Policy

We all know that backups must be scheduled periodically. Full backups (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, `InnoDB Hot Backup` provides online non-blocking physical backup of the `InnoDB` data files, and `mysqldump` provides online logical backup. This discussion uses `mysqldump`.

Assume that we make a backup on Sunday at 1 PM, when load is low. The following command makes a full backup of all our `InnoDB` tables in all databases:

```
shell> mysqldump --single-transaction --all-databases > backup_sunday_1_PM.sql
```

This is an online, non-blocking backup that does not disturb the reads and writes on the tables. We assumed earlier that our tables are `InnoDB` tables, so `--single-transaction` uses a consistent read and guarantees that data seen by `mysqldump` does not change. (Changes made by other clients to `InnoDB` tables are not seen by the `mysqldump` process.) If we do also have other types of tables, we must assume that they are not changed during the backup. For example, for the `MyISAM` tables in the `mysql` database, we must assume that no administrative changes are being made to MySQL accounts during the backup.

The resulting `.sql` file produced by the `mysqldump` command contains SQL `INSERT` statements that can be used to reload the dumped tables later.

Full backups are necessary, but they are not always convenient. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that didn't change since the previous full backup. After we have made the initial full backup, it is more optimal to make incremental backups. They are smaller and take less time to produce. (The tradeoff is that at recovery time, you do not restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.)

To make incremental backups, we need to save the incremental changes. The MySQL server should always be started with the `--log-bin` option so that it stores these changes in a file while it updates data. This option enables binary logging, so that the server writes each SQL statement that updates data into a file called a MySQL binary log. Let's look at the data directory of a MySQL server that was started with the `--log-bin` option and that has been running for some days. We find these MySQL binary log files:

```
-rw-rw----  1 guilhem  guilhem     1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw----  1 guilhem  guilhem           4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw----  1 guilhem  guilhem          79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw----  1 guilhem  guilhem         508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw----  1 guilhem  guilhem   220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw----  1 guilhem  guilhem      998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw----  1 guilhem  guilhem         361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory. This file is used for replication.

The MySQL binary logs are important for recovery, because they are incremental backups. If you make sure to flush the logs when you make your full backup, then any binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump`

command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2
           --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the the data directory contains a new binary log file, gbi-chot2-bin.000007. The resulting .sql file contains these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the mysqldump command made a full backup, these lines mean two things:

• The .sql file contains all changes made before any changes written to the gbi-chot2-bin.000007 binary log file or newer.

• All data changes logged after the backup are not present in the .sql, but are present in the gbichot2-bin.000007 binary log file or newer.

On Monday at 1 PM, we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a mysqladmin flush-logs command creates gbi-chot2-bin.000008. All changes between the Sunday 1 PM full backup and Monday 1 PM are the file gbichot2-bin.000007. This incremental backup is important, so it's a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday 1 PM, execute another mysqladmin flush-logs command. All changes between Monday 1 PM and Tuesday 1 PM are the file gbichot2-bin.000008 (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2
           --all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

Note: Deleting the MySQL binary logs with mysqldump --delete-master-logs can be dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log.

The description for the PURGE MASTER LOGS statement explains what should be verified before deleting the MySQL binary logs. See Section 13.6.1.1, "PURGE MASTER LOGS Syntax".

5.8.2.2. Using Backups for Recovery

Now suppose that we have a catastrophic crash on Wednesday at 8 AM that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 PM). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 PM. To restore the changes made since then, we must use the incremental backups, that is, the gbichot2-bin.000007 and gbi-chot2-bin.000008 binary log files. Fetch them if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 PM, but still are missing the changes from that date to the date of the crash. To not miss them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not in the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device than the one on which the data directory resides. That way, the logs are not lost even if the device containing the directory is.) If we had done this, we would have the `gbichot2-bin.000009` at hand, and we could apply it to restore the most recent data changes with no loss how it was at the moment of the crash.

5.8.2.3. Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=log_name`, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this can also be good for disk load balancing (which results in a performance improvement).

- Make periodic full backups, using the last `mysqldump` command given earlier that makes an online, non-blocking backup.

- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

5.8.3. Point-in-Time Recovery

If a MySQL server has the binary log enabled, you can use the `mysqlbinlog` utility to recover data starting from a specified point in time (e.g., since your last backup) until the present or another specified point in time. For information on enabling the binary log, see Section 5.10.4, "The Binary Log". For more information on the `mysqlbinlog`, see Section 8.5, "mysqlbinlog — Utility for Processing Binary Log Files".

To be able to restore data from a binary log, you will need to know the path and name of the current binary log file. The path can tyically be found in the options file (that is, `my.cnf` or `my.ini`, depending on your system). If it's not contained in the options file, it may be given as an option at the command-line when the server is started. The option for enabling binary logging is `--log-bin`. To determine the name of the current binary log file, enter the following statement in MySQL:

```
SHOW BINLOG EVENTS \G
```

If you prefer, you could enter the following from the command line instead:

```
mysql --user=root -pmy_pwd -e 'SHOW BINLOG EVENTS \G'
```

Replace the password *my_pwd* with the *root* password for your server.

5.8.3.1. Specifying Times for Recovery

As of version 4.1.4 of MySQL, the `--start-date` and the `--stop-date` options are available for `mysqlbinlog` to specify the start and end times in the `DATETIME` format. As an example, suppose that exactly at 10:00 a.m. today (today being April 20, 2005) an SQL statement was executed which deleted a large table. To restore the table and data, you could restore the previous night's backup, and then enter the following:

```
mysqlbinlog --stop-date="2005-04-20 9:59:59" /var/log/mysql/bin.123456 \
    | mysql -u root -pmypwd
```

This will recover all of the data up until the date and time given as a `DATETIME` format for the `--stop-date` option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably want to recover the activity that occurred afterwards, as well. Based on this, you could run the `mysqlbinlog` again with a start date and time like so:

```
mysqlbinlog --start-date="2005-04-20 10:01:00" /var/log/mysql/bin.123456 \
      | mysql -u root -pmypwd \
```

In this line, the SQL statements logged from 10:01 a.m. will be run. The combination of executing of the previous night's dump file and the two lines of the `mysqlbinlog` will restore everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on. You should examine the log to be sure of the exact times. The next section explains how this might be done.

5.8.3.2. Specifying Positions for Recovery

Instead of specifying dates and times, the options `--start-position` and `--stop-position` for `mysqlbinlog` could be used for specifying log positions. They work the same as the start and stop date options, except that position numbers from the log are given. Using log positions may a be more accurate recovery method, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, you could run `mysqlbinlog` for a range of times around when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
mysqlbinlog --start-date="2005-04-20 9:55:00" --stop-date="2005-04-20 10:05:00"
      /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This will create a small text file in the `/tmp` directory which will show the SQL statements around the time the deleterious SQL statement was executed. You would then open this file with a text editor and look for the statement that you don't want to repeat. Once the position numbers in the binary log are determined for stopping and resuming the recovery, make note of them. Positions are labeled with `log_pos` followed by a number. After restoring the previous backup file, using the position numbers, you would then enter something like the following from the command-line:

```
mysqlbinlog --stop-position="368312" /var/log/mysql/bin.123456 \
      | mysql -u root -pmypwd

mysqlbinlog --start-position="368315" /var/log/mysql/bin.123456 \
      | mysql -u root -pmypwd \
```

The first line above will recover all of the transactions up until the stop position given. The next line will recover all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times that the transactions were executed.

5.8.4. Table Maintenance and Crash Recovery

The following sections discuss how to use `myisamchk` to check or repair `MyISAM` tables (tables with `.MYI` and `.MYD` files). The same concepts apply to using `isamchk` to check or repair `ISAM` tables (tables with `.ISM` and `.ISD` files). See Chapter 14, *MySQL Storage Engines and Table Types*.

You can use the `myisamchk` utility to get information about your database tables or to check, repair, or optimize them. The following sections describe how to invoke `myisamchk` (including a description of its options), how to set up a table maintenance schedule, and how to use `myisamchk` to perform its various functions.

Even though table repair with `myisamchk` is quite secure, it's always a good idea to make a backup *before* doing a repair (or any maintenance operation that could make a lot of changes to a table)

myisamchk operations that affect indexes can cause FULLTEXT indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this, read the instructions in Section 5.8.5.1, "General Options for myisamchk".

In many cases, you may find it simpler to do MyISAM table maintenance using the SQL statements that perform operations that myisamchk can do:

- To check or repair MyISAM tables, use CHECK TABLE or REPAIR TABLE.

- To optimize MyISAM tables, use OPTIMIZE TABLE.

- To analyze MyISAM tables, use ANALYZE TABLE.

These statements were introduced in different versions, but all are available from MySQL 3.23.14 on. See Section 13.5.2.1, "ANALYZE TABLE Syntax", Section 13.5.2.3, "CHECK TABLE Syntax", Section 13.5.2.5, "OPTIMIZE TABLE Syntax", and Section 13.5.2.6, "REPAIR TABLE Syntax". The statements can be used directly, or by means of the mysqlcheck client program, which provides a command-line interface to them.

One advantage of these statements over myisamchk is that the server does all the work. With my-isamchk, you must make sure that the server does not use the tables at the same time. Otherwise, there can be unwanted interaction between myisamchk and the server.

5.8.5. myisamchk — MyISAM Table-Maintenance Utility

The myisamchk utility gets information about your database tables or checks, repairs, or optimizes them. myisamchk works with MyISAM tables (tables with .MYI and .MYD files). A related utility, isamchk, works with ISAM tables (tables with .ISM and .ISD files).

Invoke myisamchk like this:

```
shell> myisamchk [options] tbl_name ...
```

The options specify what you want myisamchk to do. They are described in the following sections. You can also get a list of options by invoking myisamchk --help.

With no options, myisamchk simply checks your table as the default operation. To get more information or to tell myisamchk to take corrective action, specify options as described in the following discussion.

tbl_name is the database table you want to check or repair. If you run myisamchk somewhere other than in the database directory, you must specify the path to the database directory, because myisamchk has no idea where the database is located. In fact, myisamchk doesn't actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the myisamchk command line if you wish. You can also specify a table by naming its index file (the file with the .MYI suffix). This allows you to specify all tables in a directory by using the pattern *.MYI. For example, if you are in a database directory, you can check all the MyISAM tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all MyISAM and ISAM tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
shell> isamchk --silent /path/to/datadir/*/*.ISM
```

If you want to check all MyISAM and ISAM tables and repair any that are corrupted, you can use the following commands:

```
shell> myisamchk --silent --force --fast --update-state \
          -O key_buffer=64M -O sort_buffer=64M \
          -O read_buffer=1M -O write_buffer=1M \
          /path/to/datadir/*/*.MYI
shell> isamchk --silent --force -O key_buffer=64M \
          -O sort_buffer=64M -O read_buffer=1M -O write_buffer=1M \
          /path/to/datadir/*/*.ISM
```

These commands assume that you have more than 64MB free. For more information about memory allocation with myisamchk, see Section 5.8.5.5, "myisamchk Memory Usage".

You must ensure that no other program is using the tables while you are running myisamchk. Otherwise, when you run myisamchk, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the mysqld server) that hasn't yet closed the file or that has died without closing the file properly.

If mysqld is running, you must force it to flush any table modifications that are still buffered in memory by using FLUSH TABLES. You should then ensure that no one is using the tables while you are running myisamchk. The easiest way to avoid this problem is to use CHECK TABLE instead of myisamchk to check tables.

5.8.5.1. General Options for `myisamchk`

The options described in this section can be used for any type of table maintenance operation performed by myisamchk. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help, -?`

  Display a help message and exit.

- `--debug=debug_options, -# debug_options`

  Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`.

- `--silent, -s`

  Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make myisamchk very silent.

- `--verbose, -v`

  Verbose mode. Print more information. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version, -V`

  Display version information and exit.

- `--wait, -w`

  Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. Note that if you are running `mysqld` with the `--skip-external-locking` option, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` options:

Variable	Default Value
`decode_bits`	9
`ft_max_word_len`	version-dependent
`ft_min_word_len`	4
`ft_stopword_file`	built-in list
`key_buffer_size`	523264
`myisam_block_size`	1024
`read_buffer_size`	262136
`sort_buffer_size`	2097144
`sort_key_blocks`	16
`write_buffer_size`	262136

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. However, this syntax is deprecated as of MySQL 4.0.

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover`.

`key_buffer_size` is used when you are checking the table with `--extend-check` or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover`.

- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks. It is available as of MySQL 4.0.0.

The `ft_min_word_len` and `ft_max_word_len` variables are available as of MySQL 4.0.0.

`ft_stopword_file` is available as of MySQL 4.0.19.

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes. `ft_stopword_file` names the stopword file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

5.8.5.2. Check Options for `myisamchk`

`myisamchk` supports the following options for table checking operations:

- `--check`, `-c`

  Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- `--check-only-changed`, `-C`

  Check only tables that have changed since the last check.

- `--extend-check`, `-e`

  Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, `myisamchk` or `myisamchk --medium-check` should be able to determine whether there are any errors in the table.

  If you are using `--extend-check` and have plenty of memory, setting the `key_buffer_size` variable to a large value helps the repair operation run faster.

- `--fast`, `-F`

  Check only tables that haven't been closed properly.

- `--force`, `-f`

  Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type

is the same as that specified with the `--repair` or `-r` option.

- `--information, -i`

  Print informational statistics about the table that is checked.

- `--medium-check, -m`

  Do a check that is faster than an `--extend-check` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only, -T`

  Don't mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that doesn't use locking, such as `mysqld` when run with the `--skip-external-locking` option.

- `--update-state, -U`

  Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with the `--skip-external-locking` option.

5.8.5.3. Repair Options for `myisamchk`

`myisamchk` supports the following options for table repair operations:

- `--backup, -B`

  Make a backup of the `.MYD` file as `file_name-time.BAK`

- `--character-sets-dir=path`

  The directory where character sets are installed. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--correct-checksum`

  Correct the checksum information for the table.

- `--data-file-length=len, -D len`

  Maximum length of the data file (when re-creating data file when it's "full").

- `--extend-check, -e`

  Do a repair that tries to recover every possible row from the data file. Normally this also finds a lot of garbage rows. Don't use this option unless you are totally desperate.

- `--force, -f`

  Overwrite old temporary files (files with names like `tbl_name.TMD`) instead of aborting.

- `--keys-used=val, -k val`

  For `myisamchk`, the option value is a bit-value indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. For `isamchk`, the option value indicates that only the first `val` of the table indexes should be updated. In either case, an option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r` or (`isamchk -r`).

- `--no-symlinks, -l`

  Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option doesn't exist as of MySQL 4.0, because versions from 4.0 on do not remove symlinks during repair operations.

- `--parallel-recover, -p`

  Uses the same technique as `-r` and `-n`, but creates all the keys in parallel, using different threads. This option was added in MySQL 4.0.2. *This is alpha code. Use at your own risk!*

- `--quick, -q`

  Achieve a faster repair by not modifying the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover, -r`

  Do a repair that can fix almost any problem except unique keys that aren't unique (which is an extremely unlikely error with `ISAM`/`MyISAM` tables). If you want to recover a table, this is the option to try first. You should try `-o` only if `myisamchk` reports that the table can't be recovered by `-r`. (In the unlikely case that `-r` fails, the data file is still intact.)

  If you have lots of memory, you should increase the value of `sort_buffer_size`.

- `--safe-recover, -o`

  Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `-r`, but can handle a couple of very unlikely cases that `-r` cannot. This recovery method also uses much less disk space than `-r`. Normally, you should repair first with `-r`, and then with `-o` only if `-r` fails.

  If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-character-set=name`

  Change the character set used by the table indexes. This option was replaced by `--set-collation` in MySQL 4.1.1/5.0.3.

- `--set-collation=name`

  Change the collation used to sort table indexes. The character set name is implied by the first part of the collation name. This option was added in MySQL 4.1.11/5.0.3.

- `--sort-recover, -n`

  Force `myisamchk` to use sorting to resolve the keys even if the temporary files should be very big.

- `--tmpdir=path, -t path`

  Path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. Starting from MySQL 4.1, `tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names should be colon ('`:`') on Unix and semicolon ('`;`') on Windows, NetWare, and OS/2.

- `--unpack, -u`

  Unpack a table that was packed with `myisampack`.

5.8.5.4. Other Options for `myisamchk`

myisamchk supports the following options for actions other than table checks and repairs:

- --analyze, -a

  Analyze the distribution of keys. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which keys it should use. To obtain information about the distribution, use a myisamchk --description --verbose *tbl_name* command or the SHOW KEYS FROM *tbl_name* statement.

- --description, -d

  Print some descriptive information about the table.

- --set-auto-increment[=*value*], -A[*value*]

  Force AUTO_INCREMENT numbering for new records to start at the given value (or higher, if there are existing records with AUTO_INCREMENT values this large). If *value* is not specified, AUTO_INCREMENT number for new records begins with the largest value currently in the table, plus one.

- --sort-index, -S

  Sort the index tree blocks in high-low order. This optimizes seeks and makes table scanning by key faster.

- --sort-records=*N*, -R *N*

  Sort records according to a particular index. This makes your data much more localized and may speed up range-based SELECT and ORDER BY operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use SHOW KEYS, which displays a table's indexes in the same order that myisamchk sees them. Indexes are numbered beginning with 1.

  If keys are not packed (PACK_KEYS=0)), they have the same length, so when myisamchk sorts and moves records, it just overwrites record offsets in the index. If keys are packed (PACK_KEYS=1), myisamchk must unpack key blocks first, then recreate indexes and pack the key blocks again. (In this case, recreating indexes is faster than updating offsets for each index.)

5.8.5.5. `myisamchk` Memory Usage

Memory allocation is important when you run myisamchk. myisamchk uses no more memory than you specify with the -O options. If you are going to use myisamchk on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get myisamchk to operate faster. For example, if you have more than 32MB RAM, you could use options such as these (in addition to any other options you might specify):

```
shell> myisamchk -O sort=16M -O key=16M -O read=1M -O write=1M ...
```

Using -O sort=16M should probably be enough for most cases.

Be aware that myisamchk uses temporary files in TMPDIR. If TMPDIR points to a memory filesystem, you may easily get out of memory errors. If this happens, set TMPDIR to point at some directory located on a filesystem with more space and run myisamchk again.

When repairing, myisamchk also needs a lot of disk space:

- Double the size of the data file (the original one and a copy). This space is not needed if you do a repair with --quick; in this case, only the index file is re-created. This space is needed on

the same filesystem as the original data file! (The copy is created in the same directory as the original.)

- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space is needed on the same filesystem as the original index file!

- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space for a sort buffer. The amount of space required is:

  ```
  (largest_key + row_pointer_length) * number_of_rows * 2
  ```

  You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name`. This space is allocated in the temporary directory (specified by TMPDIR or `--tmpdir=path`).

If you have a problem with disk space during repair, you can try to use `--safe-recover` instead of `--recover`.

5.8.5.6. Using `myisamchk` for Crash Recovery

If you run `mysqld` with `--skip-external-locking` (which is the default on some systems, such as Linux), you can't reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be sure that no one is accessing the tables through `mysqld` while you run `myisamchk`, you only have to do `mysqladmin flush-tables` before you start checking the tables. If you can't guarantee this, then you must stop `mysqld` while you check the tables. If you run `myisamchk` while `mysqld` is updating the tables, you may get a warning that a table is corrupt even when it isn't.

If you are not using `--skip-external-locking`, you can use `myisamchk` to check tables at any time. While you do this, all clients that try to update the table wait until `myisamchk` is ready before continuing.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if you are using `--skip-external-locking`). If you don't take down `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

This section describes how to check for and deal with data corruption in MySQL databases. If your tables get corrupted frequently you should try to find the reason why. See Section A.4.2, "What to Do If MySQL Keeps Crashing".

The `MyISAM` table section contains reason for why a table could be corrupted. See Section 14.1.4, "`MyISAM` Table Problems".

When performing crash recovery, it is important to understand that each `MyISAM` table `tbl_name` in a database corresponds to three files in the database directory:

File	Purpose
`tbl_name.frm`	Definition (format) file
`tbl_name.MYD`	Data file
`tbl_name.MYI`	Index file

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use -

-quick, myisamchk does not create a temporary .MYD file, but instead assumes that the .MYD file is correct and only generates a new index file without touching the .MYD file. This is safe, because myisamchk automatically detects whether the .MYD file is corrupt and aborts the repair if it is. You can also specify the --quick option twice to myisamchk. In this case, myisamchk does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the .MYD file. Normally the use of two --quick options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup before running myisamchk.

5.8.5.7. How to Check `MyISAM` Tables for Errors

To check a MyISAM table, use the following commands:

- myisamchk *tbl_name*

  This finds 99.99% of all errors. What it can't find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run myisamchk without options or with either the -s or --silent option.

- myisamchk -m *tbl_name*

  This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all keys in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- myisamchk -e *tbl_name*

  This does a complete and thorough check of all data (-e means "extended check"). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, myisamchk stops after the first error it finds. If you want to obtain more information, you can add the --verbose (-v) option. This causes myisamchk to keep going, up through a maximum of 20 errors.

- myisamchk -e -i *tbl_name*

  Like the previous command, but the -i option tells myisamchk to print some informational statistics, too.

In most cases, a simple myisamchk with no arguments other than the table name is sufficient to check a table.

5.8.5.8. How to Repair Tables

The discussion in this section describes how to use myisamchk on MyISAM tables (extensions .MYI and .MYD). If you are using ISAM tables (extensions .ISM and .ISD), you should use isamchk instead; the concepts are similar.

If you are using MySQL 3.23.16 and above, you can (and should) use the CHECK TABLE and REPAIR TABLE statements to check and repair MyISAM tables. See Section 13.5.2.3, "CHECK TABLE Syntax" and Section 13.5.2.6, "REPAIR TABLE Syntax".

The symptoms of a corrupted table include queries that abort unexpectedly and observable errors such as these:

- *tbl_name*.frm is locked against change

- Can't find file *tbl_name*.MYI (Errcode: *nnn*)

- Unexpected end of file

- Record file is crashed

- Got error *nnn* from table handler

To get more information about the error you can run `perror` *nnn*, where *nnn* is the error number. The following example shows how to use `perror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> perror 126 127 132 134 135 136 141 144 145
126 = Index file is crashed / Wrong file format
127 = Record-file is crashed
132 = Old database file
134 = Record was already deleted (or record file crashed)
135 = No more room in record file
136 = No more room in index file
141 = Duplicate unique key or constraint on write or update
144 = Table is crashed and last repair failed
145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you have to use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you don't know the current table option values, use `SHOW CREATE TABLE tbl_name`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

The options that you can use for table maintenance with `myisamchk` and `isamchk` are described in several of the earlier subsections of Section 5.8.5, "myisamchk — MyISAM Table-Maintenance Utility".

The following section is for the cases where the above command fails or if you want to use the extended features that `myisamchk` and `isamchk` provide.

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still alive for a while after `mysqladmin` returns, until all queries are stopped and all keys have been flushed to disk.

Stage 1: Checking your tables

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is down, you should use the `--update-state` option to tell `myisamchk` to mark the table as 'checked'.

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get weird errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 2: Easy safe repair

Note: If you want a repair operation to go much faster, you should set the values of the

`sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk` or `isamchk`.

First, try `myisamchk -r -q tbl_name` (`-r -q` means "quick recovery mode"). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.

2. Use `myisamchk -r tbl_name` (`-r` means "recovery mode"). This removes incorrect records and deleted records from the data file and reconstructs the index file.

3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode doesn't (but is slower).

If you get weird errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it's necessary to create a new index file. Do so as follows:

1. Move the data file to some safe place.

2. Use the table description file to create new (empty) data and index files:

    ```
    shell> mysql db_name
    mysql> SET AUTOCOMMIT=1;
    mysql> TRUNCATE TABLE tbl_name;
    mysql> quit
    ```

    If your version of MySQL doesn't have `TRUNCATE TABLE`, use `DELETE FROM tbl_name` instead.

3. Copy the old data file back onto the newly created data file. (Don't just move the old file back onto the new file; you want to retain a copy in case something goes wrong.)

Go back to Stage 2. `myisamchk -r -q` should work. (This shouldn't be an endless loop.)

As of MySQL 4.0.2, you can also use `REPAIR TABLE tbl_name USE_FRM`, which performs the whole procedure automatically.

Stage 4: Very difficult repair

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file isn't changed after the table is created:

1. Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.

2. If you don't have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

5.8.5.9. Table Optimization

To coalesce fragmented records and eliminate wasted space resulting from deleting or updating records, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the SQL `OPTIMIZE TABLE` statement. `OPTIMIZE TABLE` does a repair of the table and a key analysis, and also sorts the index tree to give faster key lookups. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See Section 13.5.2.5, "`OPTIMIZE TABLE` Syntax".

`myisamchk` also has a number of other options you can use to improve the performance of a table:

- `-S, --sort-index`

- `-R index_num, --sort-records=index_num`

- `-a, --analyze`

For a full description of the options, see Section 5.8.5, "myisamchk — MyISAM Table-Maintenance Utility".

5.8.6. Setting Up a Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair `MyISAM` tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. These are available starting with MySQL 3.23.16. See Section 13.5.2.3, "`CHECK TABLE` Syntax" and Section 13.5.2.6, "`REPAIR TABLE` Syntax".

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It's also a good idea to check tables when the server starts. For example, whenever the machine has done a restart in the middle of an update, you usually need to check all the tables that could have been affected. (These are "expected crashed tables.") To check `MyISAM` tables automatically, start the server with the `--myisam-recover` option, available as of MySQL 3.23.25. If your server is too old to support this option, you could add a test to `mysqld_safe` that runs `myisamchk` to check all tables that have been modified during the last 24 hours if there is an old `.pid` (process ID) file left after a restart. (The `.pid` file is created by `mysqld` when it starts and removed when it terminates normally. The presence of a `.pid` file at system startup time indicates that `mysqld` terminated abnormally.)

An even better test would be to check any table whose last-modified time is more recent than that of the `.pid` file.

You should also check your tables regularly during normal system operation. At MySQL AB, we run a `cron` job to check all our important tables once a week, using a line like this in a `crontab` file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that we can examine and repair them when needed.

Because we haven't had any unexpectedly crashed tables (tables that become corrupted for reasons other than hardware trouble) for a couple of years (this is really true), once a week is more than

enough for us.

We recommend that to start with, you execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours, until you come to trust MySQL as much as we do.

Normally, MySQL tables need little maintenance. If you are changing `MyISAM` tables with dynamic-sized rows (tables with `VARCHAR`, `BLOB`, or `TEXT` columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time (once a month?).

You can do this by using `OPTIMIZE TABLE` on the tables in question. Or, if you can stop the `mysqld` server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index -O sort_buffer_size=16M */*.MYI
```

For `ISAM` tables, the command is similar:

```
shell> isamchk -r -s --sort-index -O sort_buffer_size=16M */*.ISM
```

5.8.7. Getting Information About a Table

To obtain a description of a table or statistics about it, use the commands shown here. We explain some of the information in more detail later:

*   `myisamchk -d` *tbl_name*

    Runs `myisamchk` in "describe mode" to produce a description of your table. If you start the MySQL server using the `--skip-external-locking` option, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` doesn't change the table in describe mode, there is no risk of destroying data.

*   `myisamchk -d -v` *tbl_name*

    Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about what it is doing.

*   `myisamchk -eis` *tbl_name*

    Shows only the most important information from a table. This operation is slow because it must read the entire table.

*   `myisamchk -eiv` *tbl_name*

    This is like `-eis`, but tells you what is being done.

Sample output for some of these commands follows. They are based on a table with these data and index file sizes:

```
-rw-rw-r--   1 monty    tcx       317235748 Jan 12 17:30 company.MYD
-rw-rw-r--   1 davida   tcx        96482304 Jan 12 18:35 company.MYM
```

Example of `myisamchk -d` output:

```
MyISAM file:      company.MYI
Record format:    Fixed length
Data records:     1403698  Deleted blocks:          0
Recordlength:     226

table description:
```

```
Key Start Len Index    Type
1   2     8   unique   double
2   15    10  multip.  text packed stripped
3   219   8   multip.  double
4   63    10  multip.  text packed stripped
5   167   2   multip.  unsigned short
6   177   4   multip.  unsigned long
7   155   4   multip.  text
8   138   4   multip.  unsigned long
9   177   4   multip.  unsigned long
    193   1            text
```

Example of `myisamchk -d -v` output:

```
MyISAM file:          company
Record format:        Fixed length
File-version:         1
Creation time:        1999-10-30 12:12:51
Recover time:         1999-10-31 19:13:01
Status:               checked

Explanations for the types of information `myisamchk` produces are given here. "Keyfile" refers to the index file. "Record" and "row" are synonymous.

- `MyISAM file`

  Name of the `MyISAM` (index) file.

- `File-version`

  Version of `MyISAM` format. Currently always 2.

- `Creation time`

When the data file was created.

- `Recover time`

  When the index/data file was last reconstructed.

- `Data records`

  How many records are in the table.

- `Deleted blocks`

  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 5.8.5.9, "Table Optimization".

- `Datafile parts`

  For dynamic record format, this indicates how many data blocks there are. For an optimized table without fragmented records, this is the same as `Data records`.

- `Deleted data`

  How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See Section 5.8.5.9, "Table Optimization".

- `Datafile pointer`

  The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a record address. For dynamic tables, this is a byte address.

- `Keyfile pointer`

  The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- `Max datafile length`

  How long the table data file can become, in bytes.

- `Max keyfile length`

  How long the table index file can become, in bytes.

- `Recordlength`

  How much space each record takes, in bytes.

- `Record format`

  The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`.

- `table description`

  A list of all keys in the table. For each key, `myisamchk` displays some low-level information:

  - `Key`

    This key's number.

  - `Start`

    Where in the record this index part starts.

- Len

  How long this index part is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column.

- Index

  Whether a key value can exist multiple times in the index. Values are `unique` or `multip`. (multiple).

- Type

  What data type this index part has. This is a `MyISAM` data type with the options `packed`, `stripped`, or `empty`.

- Root

  Address of the root index block.

- Blocksize

  The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- Rec/key

  This is a statistical value used by the optimizer. It tells how many records there are per value for this key. A unique key always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

For the table shown in the examples, there are two `table description` lines for the ninth index. This indicates that it is a multiple-part index with two parts.

- Keyblocks used

  What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, as for the table in the examples, the values are very high (very near the theoretical maximum).

- Packed

  MySQL tries to pack keys with a common suffix. This can only be used for indexes on `CHAR`, `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the third example above, the fourth key is 10 characters long and a 60% reduction in space is achieved.

- Max levels

  How deep the B-tree for this key is. Large tables with long key values get high values.

- Records

  How many rows are in the table.

- M.recordlength

  The average record length. This is the exact record length for tables with fixed-length records, because all records have the same length.

- Packed

MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

  What percentage of the data file is used.

- `Empty space`

  What percentage of the data file is unused.

- `Blocks/Record`

  Average number of blocks per record (that is, how many links a fragmented record is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too big, you can reorganize the table. See Section 5.8.5.9, "Table Optimization".

- `Recordblocks`

  How many blocks (links) are used. For fixed format, this is the same as the number of records.

- `Deleteblocks`

  How many blocks (links) are deleted.

- `Recorddata`

  How many bytes in the data file are used.

- `Deleted data`

  How many bytes in the data file are deleted (unused).

- `Lost space`

  If a record is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

- `Linkdata`

  When the dynamic table format is used, record fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.

If a table has been compressed with `myisampack`, `myisamchk -d` prints additional information about each table column. See Section 8.2, "myisampack — Generate Compressed, Read-Only My-ISAM Tables", for an example of this information and a description of what it means.

5.9. MySQL Localization and International Usage

This section describes how to configure the server to use different character sets. It also discusses how to set the server's time zone and enable per-connection time zone support.

5.9.1. The Character Set Used for Data and Sorting

By default, MySQL uses the cp1252 (Latin1) character set with sorting according to Swedish/ Finnish rules. These defaults are suitable for the United States and most of western Europe.

All MySQL binary distributions are compiled with `--with-extra-charsets=complex`. This

adds code to all standard programs that enables them to handle `latin1` and all multi-byte character sets within the binary. Other character sets are loaded from a character-set definition file when needed.

The character set determines what characters are allowed in names. It also determines how strings are sorted by the `ORDER BY` and `GROUP BY` clauses of the `SELECT` statement.

You can change the character set with the `--default-character-set` option when you start the server. The character sets available depend on the `--with-charset=`*charset* and `--with-extra-charsets=`*list-of-charsets* | `complex` | `all` | `none` options to `configure`, and the character set configuration files listed in `SHAREDIR/charsets/Index`. See Section 2.8.2, "Typical `configure` Options".

As of MySQL 4.1.1, you can also change the character set collation with the `--default-collation` option when you start the server. The collation must be a legal collation for the default character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.) See Section 2.8.2, "Typical `configure` Options".

If you change the character set when running MySQL, that may also change the sort order. Consequently, you must run `myisamchk -r -q --set-character-set=`*charset* on all tables, or your indexes may not be ordered correctly.

When a client connects to a MySQL server, the server indicates to the client what the server's default character set is. The client switches to use this character set for this connection.

You should use `mysql_real_escape_string()` when escaping strings for an SQL query. `mysql_real_escape_string()` is identical to the old `mysql_escape_string()` function, except that it takes the `MYSQL` connection handle as the first parameter so that the appropriate character set can be taken into account when escaping characters.

If the client is compiled with different paths than where the server is installed and the user who configured MySQL didn't include all character sets in the MySQL binary, you must tell the client where it can find the additional character sets it needs if the server runs with a different character set than the client.

You can do this by specifying a `--character-sets-dir` option to indicate the path to the directory in which the dynamic MySQL character sets are stored. For example, you can put the following in an option file:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets
```

You can force the client to use specific character set as follows:

```
[client]
default-character-set=charset
```

This is normally unnecessary, however.

5.9.1.1. Using the German Character Set

In MySQL 4.0, to get German sorting order, you should start `mysqld` with a `--default-character-set=latin1_de` option. This affects server behavior in several ways:

- When sorting and comparing strings, the following mapping is performed on the strings before doing the comparison:

```
ä  ->  ae
ö  ->  oe
ü  ->  ue
ß  ->  ss
```

- All accented characters are converted to their unaccented uppercase counterpart. All letters are converted to uppercase.

- When comparing strings with `LIKE`, the one-character to two-character mapping is not done. All letters are converted to uppercase. Accents are removed from all letters except Ü, ü, Ö, ö, Ä, and ä.

In MySQL 4.1 and up, character set and collation are specified separately. You should select the `latin1` character set and either the `latin1_german1_ci` or `latin1_german2_ci` collation. For example, to start the server with the `latin1_german1_ci` collation, use the `--character-set-server=latin1` and `--collation-server=latin1_german1_ci` options.

For information on the differences between these two collations, see Section 10.11.2, "West European Character Sets".

5.9.2. Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can also be displayed in any of these other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish.

To start `mysqld` with a particular language for error messages, use the `--language` or `-L` option. The option value can be a language name or the full path to the error message file. For example:

```
shell> mysqld --language=swedish
```

Or:

```
shell> mysqld --language=/usr/local/share/swedish
```

The language name should be specified in lowercase.

The language files are located (by default) in the `share/LANGUAGE` directory under the MySQL base directory.

To change the error message file, you should edit the `errmsg.txt` file, and then execute the following command to generate the `errmsg.sys` file:

```
shell> comp_err errmsg.txt errmsg.sys
```

If you upgrade to a newer version of MySQL, remember to repeat your changes with the new `errmsg.txt` file.

5.9.3. Adding a New Character Set

This section discusses the procedure for adding add another character set to MySQL. You must have a MySQL source distribution to use these instructions.

To choose the proper procedure, decide whether the character set is simple or complex:

- If the character set does not need to use special string collating routines for sorting and does not need multi-byte character support, it is simple.

- If it needs either of those features, it is complex.

For example, `latin1` and `danish` are simple character sets, whereas `big5` and `czech` are complex character sets.

In the following procedures, the name of your character set is represented by *MYSET*.

For a simple character set, do the following:

1. Add *MYSET* to the end of the `sql/share/charsets/Index` file. Assign a unique number to it.

2. Create the file `sql/share/charsets/MYSET.conf`. (You can use a copy of `sql/share/charsets/latin1.conf` as the basis for this file.)

   The syntax for the file is very simple:

   - Comments start with a '#' character and proceed to the end of the line.

   - Words are separated by arbitrary amounts of whitespace.

   - When defining the character set, every word must be a number in hexadecimal format.

   - The `ctype` array takes up the first 257 words. The `to_lower[]`, `to_upper[]` and `sort_order[]` arrays take up 256 words each after that.

   See Section 5.9.4, "The Character Definition Arrays".

3. Add the character set name to the `CHARSETS_AVAILABLE` and `COMPILED_CHARSETS` lists in `configure.in`.

4. Reconfigure, recompile, and test.

For a complex character set, do the following:

1. Create the file `strings/ctype-MYSET.c` in the MySQL source distribution.

2. Add *MYSET* to the end of the `sql/share/charsets/Index` file. Assign a unique number to it.

3. Look at one of the existing `ctype-*.c` files (such as `strings/ctype-big5.c`) to see what needs to be defined. Note that the arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See Section 5.9.4, "The Character Definition Arrays".

4. Near the top of the file, place a special comment like this:

   ```
   /*
    * This comment is parsed by configure to create ctype.c,
    * so don't change it unless you know what you are doing.
    *
    * .configure. number_MYSET=MYNUMBER
    * .configure. strxfrm_multiply_MYSET=N
    * .configure. mbmaxlen_MYSET=N
    */
   ```

   The `configure` program uses this comment to include the character set into the MySQL library automatically.

   The `strxfrm_multiply` and `mbmaxlen` lines are explained in the following sections. You

need include them only if you need the string collating functions or the multi-byte character set functions, respectively.

5. You should then create some of the following functions:

   - `my_strncoll_`*MYSET*`()`

   - `my_strcoll_`*MYSET*`()`

   - `my_strxfrm_`*MYSET*`()`

   - `my_like_range_`*MYSET*`()`

   See Section 5.9.5, "String Collating Support".

6. Add the character set name to the `CHARSETS_AVAILABLE` and `COMPILED_CHARSETS` lists in `configure.in`.

7. Reconfigure, recompile, and test.

The `sql/share/charsets/README` file includes additional instructions.

If you want to have the character set included in the MySQL distribution, mail a patch to the MySQL `internals` mailing list. See Section 1.7.1.1, "The MySQL Mailing Lists".

5.9.4. The Character Definition Arrays

`to_lower[]` and `to_upper[]` are simple arrays that hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
to_lower['A'] should contain 'a'
to_upper['a'] should contain 'A'
```

`sort_order[]` is a map indicating how characters should be ordered for comparison and sorting purposes. Quite often (but not for all character sets) this is the same as `to_upper[]`, which means that sorting is case-insensitive. MySQL sorts characters based on the values of `sort_order[]` elements. For more complicated sorting rules, see the discussion of string collating in Section 5.9.5, "String Collating Support".

`ctype[]` is an array of bit values, with one element for one character. (Note that `to_lower[]`, `to_upper[]`, and `sort_order[]` are indexed by character value, but `ctype[]` is indexed by character value + 1. This is an old legacy convention to be able to handle `EOF`.)

You can find the following bitmask definitions in `m_ctype.h`:

```
#define _U      01        /* Uppercase */
#define _L      02        /* Lowercase */
#define _N      04        /* Numeral (digit) */
#define _S      010       /* Spacing character */
#define _P      020       /* Punctuation */
#define _C      040       /* Control character */
#define _B      0100      /* Blank */
#define _X      0200      /* heXadecimal digit */
```

The `ctype[]` entry for each character should be the union of the applicable bitmask values that describe the character. For example, `'A'` is an uppercase character (`_U`) as well as a hexadecimal digit (`_X`), so `ctype['A'+1]` should contain the value:

```
_U + _X = 01 + 0200 = 0201
```

5.9.5. String Collating Support

If the sorting rules for your language are too complex to be handled with the simple `sort_order[]` table, you need to use the string collating functions.

The best documentation for this is the existing character sets. Look at the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets for examples.

You must specify the `strxfrm_multiply_MYSET=N` value in the special comment at the top of the file. *N* should be set to the maximum ratio the strings may grow during `my_strxfrm_MYSET` (it must be a positive integer).

5.9.6. Multi-Byte Character Support

If you want to add support for a new character set that includes multi-byte characters, you need to use the multi-byte character functions.

The best documentation for this is the existing character sets. Look at the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets for examples. These are implemented in the `ctype-charset.c` files in the `strings` directory.

You must specify the `mbmaxlen_MYSET=N` value in the special comment at the top of the source file. *N* should be set to the size in bytes of the largest character in the set.

5.9.7. Problems With Character Sets

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- Your program has an incorrect path to where the character sets are stored. (Default `/usr/local/mysql/share/mysql/charsets`). This can be fixed by using the `--character-sets-dir` option when you run the program in question.

- The character set is a multi-byte character set that can't be loaded dynamically. In this case, you must recompile the program with support for the character set.

- The character set is a dynamic character set, but you don't have a configure file for it. In this case, you should install the configure file for the character set from a new MySQL distribution.

- If your `Index` file doesn't contain the name for the character set, your program displays the following error message:

  ```
  ERROR 1105: File '/usr/local/share/mysql/charsets/?.conf'
  not found (Errcode: 2)
  ```

  In this case, you should either get a new `Index` file or manually add the name of any missing character sets to the current file.

For `MyISAM` tables, you can check the character set name and number for a table with `myisamchk -dvv tbl_name`.

5.9.8. MySQL Server Time Zone Support

Before MySQL 4.1.3, you can set the time zone for the server with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`.

The allowable values for `--timezone` or `TZ` are system-dependent. Consult your operating system documentation to see what values are acceptable.

Beginning with MySQL 4.1.3, the server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` system variable.

- The server's current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial value is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone. The initial value can be specified explicitly with the `--default-time-zone=timezone` option. If you have the `SUPER` privilege, you can set the global value at runtime with this statement:

  ```
  mysql> SET GLOBAL time_zone = timezone;
  ```

- Per-connection time zones. Each client that connects has its own time zone setting, given by the session `time_zone` variable. Initially this is the same as the global `time_zone` variable, but can be reset with this statement:

  ```
  mysql> SET time_zone = timezone;
  ```

The current values of the global and per-connection time zones can be retrieved like this:

```
mysql> SELECT @@global.time_zone, @@session.time_zone;
```

`timezone` values can be given as strings indicating an offset from UTC, such as `'+10:00'` or `'-6:00'`. If the time zone-related tables in the `mysql` database have been created and populated, you can also used named time zones, such as `'Europe/Helsinki'`, `'US/Eastern'`, or `'MET'`. The value `'SYSTEM'` indicates that the time zone should be the same as the system time zone. Time zone names are not case sensitive.

The MySQL installation procedure creates the time zone tables in the `mysql` database, but does not load them. You must do so manually. (If you are upgrading to MySQL 4.1.3 or later from an earlier version, you should create the tables by upgrading your `mysql` database. Use the instructions in Section 2.10.8, "Upgrading the Grant Tables".)

If your system has its own zoneinfo database (the set of files describing time zones), you should use the `mysql_tzinfo_to_sql` program for filling the time zone tables. Examples of such systems are Linux, FreeBSD, Sun Solaris, and Mac OS X. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system does not have a zoneinfo database, you can use the downloadable package described later in this section.

The `mysql_tzinfo_to_sql` program is used to load the time zone tables. On the command line, pass the zoneinfo directory pathname to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file, and to generate leap second information.

To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, initialize the leap second information like this,

where `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

If your system doesn't have a zoneinfo database (for example, Windows or HP-UX), you can use the package of pre-built time zone tables that is available for download at http://dev.mysql.com/downloads/timezones.html. This package contains `.frm`, `.MYD`, and `.MYI` files for the `MyISAM` time zone tables. These tables should belong to the `mysql` database, so you should place the files in the `mysql` subdirectory of your MySQL server's data directory. The server should be shut down while you do this.

Warning! Please don't use the downloadable package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead! Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

For information about time zone settings in replication setup please look into Section 6.7, "Replication Features and Known Problems".

5.10. The MySQL Log Files

MySQL has several different log files that can help you find out what's going on inside `mysqld`:

Log File	Types of Information Logged to File
The error log	Logs problems encountered starting, running, or stopping `mysqld`.
The isam log	Logs all changes to the `ISAM` tables. Used only for debugging the isam code.
The query log	Logs established client connections and executed statements.
The update log	Logs statements that change data. This log is deprecated.
The binary log	Logs all statements that change data. Also used for replication.
The slow log	Logs all queries that took more than `long_query_time` seconds to execute or didn't use indexes.

By default, all logs are created in the `mysqld` data directory. You can force `mysqld` to close and reopen the log files (or in some cases switch to a new log) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute `mysqladmin flush-logs` or `mysqladmin refresh`. See Section 13.5.5.2, "`FLUSH` Syntax".

If you are using MySQL replication capabilities, slave replication servers maintain additional log files called relay logs. These are discussed in Chapter 6, *Replication in MySQL.*

5.10.1. The Error Log

The error log file contains information indicating when `mysqld` was started and stopped and also any critical errors that occur while the server is running.

If `mysqld` dies unexpectedly and `mysqld_safe` needs to restart it, `mysqld_safe` writes a `restarted mysqld` message to the error log. If `mysqld` notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if `mysqld` dies. The trace can be used to determine where `mysqld` died. See Section F.1.4, "Using a Stack Trace".

Beginning with MySQL 4.0.10, you can specify where `mysqld` stores the error log file with the `--log-error[=file_name]` option. If no `file_name` value is given, `mysqld` uses the name `host_name.err` and writes the file in the data directory. (Prior to MySQL 4.0.10, the Windows error log name is `mysql.err`.) If you execute `FLUSH LOGS`, the error log is renamed with a suffix of `-old` and `mysqld` creates a new empty log file.

In older MySQL versions on Unix, error log handling was done by `mysqld_safe` which redirected the error file to *host_name*`.err`. You could change this filename by specifying a --err-log=*file_name* option to `mysqld_safe`.

If you don't specify `--log-error`, or (on Windows) if you use the `--console` option, errors are written to stderr, the standard error output. Usually this is your terminal.

On Windows, error output is always written to the `.err` file if `--console` is not given.

5.10.2. The General Query Log

If you want to know what happens within `mysqld`, you should start it with the `--log[=`*file_name*`]` or `-l [`*file_name*`]` option. If no *file_name* value is given, the default name is *host_name*`.log` This logs all connections and statements to the log file. This log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

Older versions of the `mysql.server` script (from MySQL 3.23.4 to 3.23.8) pass a `--log` option to `safe_mysqld` to enable the general query log. If you need better performance when you start using MySQL in a production environment, you can remove the `--log` option from `mysql.server` or change it to `--log-bin`. See Section 5.10.4, "The Binary Log".

`mysqld` writes statements to the query log in the order that it receives them. This may be different from the order in which they are executed. This is in contrast to the update log and the binary log, which are written after the query is executed, but before any locks are released. (The query log also contains all statements, whereas the update and binary logs do not contain statements that only select data.)

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). On Unix, you can rename the file and create a new one by using the following commands:

```
shell> mv hostname.log hostname-old.log
shell> mysqladmin flush-logs
shell> cp hostname-old.log to-backup-directory
shell> rm hostname-old.log
```

On Windows, you cannot rename the log file while the server has it open. You must stop the server and rename the log. Then restart the server to create a new log.

5.10.3. The Update Log

Note: The update log has been deprecated and replaced by the binary log. See Section 5.10.4, "The Binary Log". The binary log can do anything the old update log could do, and more. *The update log is unavailable as of MySQL 5.0.0.*

When started with the `--log-update[=`*file_name*`]` option, `mysqld` writes a log file containing all SQL statements that update data. If no *file_name* value is given, the default name is name of the host machine. If a filename is given, but it doesn't contain a leading path, the file is written in the data directory. If `file_name` doesn't have an extension, `mysqld` creates log files with names of the form *file_name*`.`*nnnnnn*, where *nnnnnn* is a number that is incremented each time you start the server or flush the logs.

Note: For this naming scheme to work, you must not create your own files with the same names as those that might be used for the log file sequence.

Update logging is smart because it logs only statements that really update data. So, an `UPDATE` or a `DELETE` with a `WHERE` that finds no rows is not written to the log. It even skips `UPDATE` statements that set a column to its existing value.

The update logging is done immediately after a query completes but before any locks are released or

any commit is done. This ensures that statements are logged in execution order.

If you want to update a database from update log files, you could do the following (assuming that your update logs have names of the form `file_name.nnnnnn`):

```
shell> ls -1 -t -r file_name.[0-9]* | xargs cat | mysql
```

`ls` is used to sort the update log filenames into the right order.

This can be useful if you have to revert to backup files after a crash and you want to redo the updates that occurred between the time of the backup and the crash.

5.10.4. The Binary Log

The binary log has replaced the old update log, which is unavailable starting from MySQL 5.0. The binary log contains all information that is available in the update log in a more efficient format and in a manner that is transactionally safe.

The binary log contains all statements which updated data or (starting from MySQL 4.1.3) could potentially have updated it (for example, a `DELETE` which matched no rows). Statements are stored in the form of "events" that describe the modifications.

The binary log also contains information about how long each statement took that updated the database. It doesn't contain statements that don't modify any data. If you want to log all statements (for example, to identify a problem query) you should use the general query log. See Section 5.10.2, "The General Query Log".

The primary purpose of the binary log is to be able to update the database during a restore operation as fully as possible, because the binary log contains all updates done after a backup was made.

The binary log is also used on master replication servers as a record of the statements to be sent to slave servers. See Chapter 6, *Replication in MySQL*.

Running the server with the binary log enabled makes performance about 1% slower. However, the benefits of the binary log for restore operations and in allowing you to set up replication generally outweigh this minor performance decrement.

When started with the `--log-bin[=file_name]` option, `mysqld` writes a log file containing all SQL commands that update data. If no `file_name` value is given, the default name is the name of the host machine followed by `-bin`. If file name is given, but it doesn't contain a path, the file is written in the data directory. It is recommended to specify a filename, see Section A.8.4, "Open Issues in MySQL" for the reason.

If you supply an extension in the log name (for example, `--log-bin=file_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log name. The number is incremented each time you start the server or flush the logs. A new binary log also is created automatically when the current log's size reaches `max_binlog_size`. A binary log may become larger than `max_binlog_size` if you are using large transactions: A transaction is written to the binary log in one piece, never split between binary logs.

To be able to know which different binary log files have been used, `mysqld` also creates a binary log index file that contains the name of all used binary log files. By default this has the same name as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

You can delete all binary log files with the `RESET MASTER` statement, or only some of them with `PURGE MASTER LOGS`. See Section 13.5.5.5, "`RESET` Syntax" and Section 13.6.1, "SQL Statements for Controlling Master Servers".

The binary log format has some known limitations which can affect recovery from backups, especially in old versions. These caveats which also affect replication are listed at Section 6.7, "Replication Features and Known Problems". One caveat which does not affect replication but only recovery with mysqlbinlog: before MySQL 4.1, mysqlbinlog could not prepare output suitable for mysql if the binary log contained interlaced statements originating from different clients that used temporary tables of the same name. This is fixed in MySQL 4.1. However, the problem still existed for LOAD DATA INFILE statements until it was fixed in MySQL 4.1.8.

Binary logging for stored routines and triggers is done as described in Section 18.4, "Binary Logging of Stored Routines and Triggers".

You can use the following options to mysqld to affect what is logged to the binary log. See also the discussion that follows this option list.

- --binlog-do-db=*db_name*

  Tells the master that it should log updates to the binary log if the current database (that is, the one selected by USE) is *db_name*. All other databases that are not explicitly mentioned are ignored. If you use this, you should ensure that you only do updates in the current database.

  Observe that there is an exception to the CREATE/ALTER/DROP DATABASE statements, which use the database manipulated to decide if it should log the statement rather than the current database.

  An example of what does not work as you might expect: If the server is started with binlog-do-db=sales, and you do USE prices; UPDATE sales.january SET amount=amount+1000;, this statement does not get written into the binary log.

- --binlog-ignore-db=*db_name*

  Tells the master that updates where the current database (that is, the one selected by USE) is *db_name* should not be stored in the binary log. If you use this, you should ensure that you only do updates in the current database.

  An example of what does not work as you might expect: If the server is started with binlog-ignore-db=sales, and you do USE prices; UPDATE sales.january SET amount=amount+1000;, this statement is not written into the binary log.

  Similar to the case for --binlog-do-db, there is an exception to the CREATE/ALTER/DROP DATABASE statements, which use the database manipulated to decide if it should log the statement rather than the current database.

To log or ignore multiple databases, specify the appropriate option multiple times, once for each database.

The server evaluates the options for logging or ignoring updates to the binary log according to the following rules. Observe that there is an exception for CREATE/ALTER/DROP DATABASE statements. In those cases, the database being *created, altered, or dropped* replaces the current database in the rules below.

1. Are there binlog-do-db or binlog-ignore-db rules?

   - No: Write the statement to the binary log and exit.

   - Yes: Go to the next step.

2. There are some rules (binlog-do-db or binlog-ignore-db or both). Is there a current database (has any database been selected by USE?)?

   - No: Do *not* write the statement, and exit.

- Yes: Go to the next step.

3. There is a current database. Are there some `binlog-do-db` rules?

    - Yes: Does the current database match any of the `binlog-do-db` rules?

        - Yes: Write the statement and exit.

        - No: Do *not* write the statement, and exit.

    - No: Go to the next step.

4. There are some `binlog-ignore-db` rules. Does the current database match any of the `binlog-ignore-db` rules?

    - Yes: Do not write the statement, and exit.

    - No: Write the query and exit.

For example, a slave running with only `binlog-do-db=sales` does not write to the binary log any statement whose current database is different from `sales` (in other words, `binlog-do-db` can sometimes mean "ignore other databases").

If you are using replication, you should not delete old binary log files until you are sure that no slave still needs to use them. One way to do this is to do `mysqladmin flush-logs` once a day and then remove any logs that are more than three days old. You can remove them manually, or preferably using `PURGE MASTER LOGS` (see Section 13.6.1, "SQL Statements for Controlling Master Servers"), which also safely updates the binary log index file for you (and which can take a date argument since MySQL 4.1)

A client with the `SUPER` privilege can disable binary logging of its own statements by using a `SET SQL_LOG_BIN=0` statement. See Section 13.5.3, "`SET` Syntax".

You can examine the binary log file with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log-file | mysql -h server_name
```

See Section 8.5, "mysqlbinlog — Utility for Processing Binary Log Files" for more information on the `mysqlbinlog` utility and how to use it.

If you are using transactions, you must use the MySQL binary log for backups instead of the old update log.

The binary logging is done immediately after a query completes but before any locks are released or any commit is done. This ensures that the log is logged in the execution order.

Updates to non-transactional tables are stored in the binary log immediately after execution. For transactional tables such as `BDB` or `InnoDB` tables, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the whole transaction to the binary log before the `COMMIT` is executed. When the thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer queries. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually did have to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` (default 4GB) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this, it fails and rolls back.

If you are using the update log or binary log, concurrent inserts are converted to normal inserts when using `CREATE ... SELECT` or `INSERT ... SELECT`. This is to ensure that you can re-create an exact copy of your tables by applying the log on a backup.

The binary log format is different in versions 3.23, 4.0, and 5.0.0. Those format changes were required to implement enhancements to replication. MySQL 4.1 has the same binary log format as 4.0. See Section 6.5, "Replication Compatibility Between MySQL Versions".

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, you can make the binary log be synchronized to disk after every Nth binary log write, with the `sync_binlog` global variable (1 being the safest value, but also the slowest). See Section 5.3.3, "Server System Variables". Even with `sync_binlog` set to 1, there is still the chance of an inconsistency between the tables content and the binary log content in case of crash. For example, if using `InnoDB` tables, and the MySQL server processes a `COMMIT` statement, it writes the whole transaction to the binary log and then commits this transaction into `InnoDB`. If it crashes between those two operations, at restart the transaction is rolled back by `InnoDB` but still exists in the binary log. This problem can be solved with the `--innodb-safe-binlog` option (available starting from MySQL 4.1.3), which adds consistency between the content of `InnoDB` tables and the binary log.

For this option to really bring safety to you, the MySQL server should also be configured to synchronize to disk, at every transaction, the binary log (`sync_binlog=1`) and (which is true by default) the `InnoDB` logs. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server cuts rolled back `InnoDB` transactions from the binary log. This ensures that the binary log reflects the exact data of `InnoDB` tables, and so, that the slave remains in sync with the master (not receiving a statement which has been rolled back).

Note that `--innodb-safe-binlog` can be used even if the MySQL server updates other storage engines than `InnoDB`. Only statements/transactions affecting `InnoDB` tables are subject to being removed from the binary log at `InnoDB`'s crash recovery. If at crash recovery the MySQL server discovers that the binary log is shorter than it should have been (that is, it lacks at least one successfully committed `InnoDB` transaction), which should not happen if `sync_binlog=1` and the disk/filesystem do an actual sync when they are requested to (some don't), it prints an error message ("The binary log <name> is shorter than its expected size"). In this case, this binary log is not correct, replication should be restarted from a fresh master's data snapshot.

Before MySQL 4.1.9, a write to a binary log file or binary log index file that failed due to a full disk or an exceeded quota resulted in corruption of the file. Starting from MySQL 4.1.9, writes to the binary log file and binary log index file are handled the same way as writes to `MyISAM` tables. See Section A.4.3, "How MySQL Handles a Full Disk".

5.10.5. The Slow Query Log

When started with the `--log-slow-queries[=`*`file_name`*`]` option, `mysqld` writes a log file containing all SQL statements that took more than `long_query_time` seconds to execute. The time to acquire the initial table locks is not counted as execution time.

If no *`file_name`* value is given, the default is the name of the host machine with a suffix of `-slow.log`. If a filename is given, but not as an absolute pathname, the file is written in the data directory.

A statement is logged to the slow query log after it has been executed and after all locks have been released. Log order may be different from execution order.

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process the slow query log using the `mysqldumpslow` command to get a summary of the queries that appear in the log.

Before MySQL 4.1, if you also use `--log-long-format` when logging slow queries, then queries that are not using indexes are logged as well. `--log-long-format` is deprecated as of MySQL version 4.1, when `--log-short-format` was introduced. (Long log format is the default setting since version 4.1.) Also note that starting with MySQL 4.1, the `--log-queries-not-using-indexes` option is available for the purpose of logging queries that do not use indexes to the slow query log. See Section 5.3.1, "`mysqld` Command-Line Options".

In MySQL 4.0, slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` were written to the slow query log. This logging was disabled in MySQL 4.1 until 4.1.13, when the `--log-slow-admin-statements` server option was added to enable you to request logging of slow administrative statements.

Queries handled by the query cache are not added to the slow query log, nor are queries that would not benefit from the presence of an index because the table has zero rows or one row.

5.10.6. Log File Maintenance

The MySQL Server can create a number of different log files that make it easy to see what is going on. See Section 5.10, "The MySQL Log Files". However, you must clean up these files regularly to ensure that the logs don't take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See Section 5.8.1, "Database Backups".

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, the script should have been installed automatically. You should be careful with this script if you are using the binary log for replication! (You should not remove binary logs until you are certain that their contents have been processed by all slaves.)

On other systems, you must install a short script yourself that you start from `cron` to handle log files.

You can force MySQL to start using new log files by using `mysqladmin flush-logs` or by using the SQL statement `FLUSH LOGS`. If you are using MySQL 3.21, you must use `mysqladmin refresh`.

A log flushing operation does the following:

- If standard logging (`--log`) or slow query logging (`--log-slow-queries`) is used, closes and reopens the log file (`mysql.log` and `` `hostname`-slow.log `` as default).

- If update logging (`--log-update`) or binary logging (`--log-bin`) is used, closes the log and opens a new log file with a higher sequence number.

If you are using only an update log, you only have to rename the log file and then flush the logs before making a backup. For example, you can do something like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mysqladmin flush-logs
```

Then make a backup and remove `mysql.old`.

5.11. Running Multiple MySQL Servers on the Same Machine

In some cases, you might want to run multiple `mysqld` servers on the same machine. You might

want to test a new MySQL release while leaving your existing production setup undisturbed. Or you may want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

To run multiple servers on a single machine, each server must have unique values for several operating parameters. These can be set on the command line or in option files. See Section 4.3, "Specifying Program Options".

At least the following options must be different for each server:

- `--port=port_num`

  `--port` controls the port number for TCP/IP connections.

- `--socket=path`

  `--socket` controls the Unix socket file path on Unix and the name of the named pipe on Windows. On Windows, it's necessary to specify distinct pipe names only for those servers that support named pipe connections.

- `--shared-memory-base-name=name`

  This option currently is used only on Windows. It designates the shared memory name used by a Windows server to allow clients to connect via shared memory. This option is new in MySQL 4.1.

- `--pid-file=path`

  This option is used only on Unix. It indicates the name of the file in which the server writes its process ID.

If you use the following log file options, they must be different for each server:

- `--log=path`
- `--log-bin=path`
- `--log-update=path`
- `--log-error=path`
- `--log-isam=path`
- `--bdb-logdir=path`

Log file options are described in Section 5.10.6, "Log File Maintenance".

If you want more performance, you can also specify the following options differently for each server, to spread the load between several physical disks:

- `--tmpdir=path`
- `--bdb-tmpdir=path`

Having different temporary directories is also recommended, to make it easier to determine which MySQL server created any given temporary file.

Generally, each server should also use a different data directory, which is specified using the –

`-datadir=path` option.

Warning: Normally you should never have two servers that update data in the same databases! This may lead to unpleasant surprises if your operating system doesn't support fault-free system locking! If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log filenames that are unique to each server. Otherwise, the servers try to log to the same files. Please note that this kind of setup only works with `ISAM`, `MyISAM` and `MERGE` tables, and not with any of the other storage engines.

The warning against sharing a data directory among servers also applies in an NFS environment. Allowing multiple MySQL servers to access a common data directory over NFS is a *bad idea*!

- The primary problem is that NFS is the speed bottleneck. It is not meant for such use.

- Another risk with NFS is that you has to come up with a way to make sure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

Make it easy for yourself: Forget about sharing a data directory among servers over NFS. A better solution is to have one computer that contains several CPUs and use an operating system that handles threads efficiently.

If you have multiple MySQL installations in different locations, normally you can specify the base installation directory for each server with the `--basedir=path` option to cause each server to use a different data directory, log files, and PID file. (The defaults for all these values are determined relative to the base directory). In that case, the only other options you need to specify are the `--socket` and `--port` options. For example, suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`. (For versions of MySQL older than 4.0, use `safe_mysqld` rather than `mysqld_safe`.)

As discussed in the following sections, it is possible to start additional servers by setting environment variables or by specifying appropriate command-line options. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it.

5.11.1. Running Multiple Servers on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters. On Windows NT-based systems, you also have the option of installing several servers as Windows services and running them that way. General instructions for running MySQL servers from the command line or as services are given in Section 2.3, "Installing MySQL on Windows". This section describes how to make sure that you start each server with different values for those startup options that must be unique per server, such as the data directory. These options are described in Section 5.11, "Running Multiple MySQL Servers on the Same Machine".

5.11.1.1. Starting Multiple Windows Servers at the Command Line

To start multiple servers manually from the command line, you can specify the appropriate options on the command line or in an option file. It's more convenient to place the options in an option file, but it's necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the filename with a `--defaults-file` option when you run it.

Suppose that you want to run `mysqld` on port 3307 with a data directory of `C:\mydata1`, and `mysqld-max` on port 3308 with a data directory of `C:\mydata2`. (To do this, make sure that before you start the servers, each data directory exists and has its own copy of the `mysql` database

that contains the grant tables.)

Then create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

Then start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld-max --defaults-file=C:\my-opts2.cnf
```

On NT, each server starts in the foreground (no new prompt appears until the server exits later); you'll need to issue those two commands in separate console windows.

To shut down the servers, you must connect to the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 shutdown
```

Servers configured as just described allow clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to allow named pipe connections, use the `mysqld-nt` or `mysqld-max-nt` servers and specify options that enable the named pipe and specify its name. Each server that supports named pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Then start the server this way:

```
C:\> C:\mysql\bin\mysqld-nt --defaults-file=C:\my-opts1.cnf
```

Modify `C:\my-opts2.cnf` similarly for use by the second server.

5.11.1.2. Starting Multiple Windows Servers as Services

On NT-based systems, a MySQL server can be run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in Section 2.3.12, "Starting MySQL as a Windows Service".

As of MySQL 4.0.2, you can install multiple servers as services. In this case, you must make sure that each server uses a different service name in addition to all the other parameters that must be unique per server.

For the following instructions, assume that you want to run the `mysqld-nt` server from two different versions of MySQL that are installed at `C:\mysql-4.0.8` and `C:\mysql-4.0.17`, respectively. (This might be the case if you're running 4.0.8 as your production server, but want to test 4.0.17 before upgrading to it.)

The following principles apply when installing a MySQL service with the `--install` or `--install-manual` option:

- If you specify no service name, the server uses the default service name of `MySQL` and the server reads options from the `[mysqld]` group in the standard option files.

- If you specify a service name after the `--install` option, the server ignores the `[mysqld]` option group and instead reads options from the group that has the same name as the service. The server reads options from the standard option files.

- If you specify a `--defaults-file` option after the service name, the server ignores the standard option files and reads options only from the `[mysqld]` group of the named file.

Note: Before MySQL 4.0.17, only a server installed using the default service name (`MySQL`) or one installed explicitly with a service name of `mysqld` read the `[mysqld]` group in the standard option files. As of 4.0.17, all servers read the `[mysqld]` group if they read the standard option files, even if they are installed using another service name. This allows you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group named after each service for use by the server installed with that service name.

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, be sure that you shut down and remove any existing MySQL services first.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 4.0.8 `mysqld-nt` using the service name of `mysqld1` and the 4.0.17 `mysqld-nt` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 4.0.8 and the `[mysqld2]` group for 4.0.17. For example, you can set up `C:\my.cnf` like this:

  ```
  # options for mysqld1 service
  [mysqld1]
  basedir = C:/mysql-4.0.8
  port = 3307
  enable-named-pipe
  socket = mypipe1

  # options for mysqld2 service
  [mysqld2]
  basedir = C:/mysql-4.0.17
  port = 3308
  enable-named-pipe
  socket = mypipe2
  ```

  Install the services as follows, using the full server pathnames to ensure that Windows registers the correct executable program for each service:

  ```
  C:\> C:\mysql-4.0.8\bin\mysqld-nt --install mysqld1
  C:\> C:\mysql-4.0.17\bin\mysqld-nt --install mysqld2
  ```

  To start the services, use the services manager, or use `NET START` with the appropriate service names:

  ```
  C:\> NET START mysqld1
  C:\> NET START mysqld2
  ```

  To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

```
C:\> NET STOP mysqld1
C:\> NET STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

  With this approach, to specify options for the 4.0.8 `mysqld-nt`, create a file `C:\my-opts1.cnf` that looks like this:

  ```
  [mysqld]
  basedir = C:/mysql-4.0.8
  port = 3307
  enable-named-pipe
  socket = mypipe1
  ```

  For the 4.0.17 `mysqld-nt`, create a file `C:\my-opts2.cnf` that looks like this:

  ```
  [mysqld]
  basedir = C:/mysql-4.0.17
  port = 3308
  enable-named-pipe
  socket = mypipe2
  ```

  Install the services as follows (enter each command on a single line):

  ```
  C:\> C:\mysql-4.0.8\bin\mysqld-nt --install mysqld1
            --defaults-file=C:\my-opts1.cnf
  C:\> C:\mysql-4.0.17\bin\mysqld-nt --install mysqld2
            --defaults-file=C:\my-opts2.cnf
  ```

  To use a `--defaults-file` option when you install a MySQL server as a service, you must precede the option with the service name.

  After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (`MySQL`), you can omit it.

5.11.2. Running Multiple Servers on Unix

The easiest way is to run multiple servers on Unix is to compile them with different TCP/IP ports and Unix socket files so that each one is listening on different network interfaces. Also, by compiling in different base directories for each installation, that automatically results in different compiled-in data directory, log file, and PID file locations for each of your servers.

Assume that an existing server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new server to have different operating parameters, use a `configure` command something like this:

```
shell> ./configure --with-tcp-port=port_number \
           --with-unix-socket-path=file_name \
           --prefix=/usr/local/mysql-4.0.17
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file pathname, and the `--prefix` value should specify an installation directory different than the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket filename:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

Note that if you specify `localhost` as a hostname, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. In MySQL 4.1, you can explicitly specify the connection protocol to use by using the `--protocol={TCP | SOCKET | PIPE | MEMORY}` option.

You don't have to compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to specify those values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=path` option to `mysqld_safe` so that the server uses a different data directory.

Another way to achieve a similar effect is to use environment variables to set the Unix socket filename and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysql_install_db --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server!

Appendix G, *Environment Variables* includes a list of other environment variables you can use to affect `mysqld`.

For automatic server execution, your startup script that is executed at boot time should execute the following command once for each server with an appropriate option file path for each command:

```
mysqld_safe --defaults-file=path
```

Each option file should contain option values specific to a given server.

On Unix, the `mysqld_multi` script is another way to start multiple servers. See Section 5.1.5, "mysqld_multi — Program for Managing Multiple MySQL Servers".

5.11.3. Using Client Programs in a Multiple-Server Environment

When you want to connect with a client program to a MySQL server that is listening to different network interfaces than those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect via TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect via TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server via a Unix socket file or a Windows named pipe.

- As of MySQL 4.1, start the client with `--protocol=tcp` to connect via TCP/IP, `--protocol=socket` to connect via a Unix socket file, `--protocol=pipe` to connect via a named pipe, or `--protocol=memory` to connect via shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or named pipe name, or a `--shared-memory-base-name` option to specify the shared memory name. Shared memory connections are supported only on Windows.

-
  On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See Appendix G, *Environment Variables*.

-
  Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See Section 4.3.2, "Using Option Files".

- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See Section 23.2.3, "C API Function Descriptions".

- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
        . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

  See Section 23.4, "MySQL Perl API".

  Other programming interfaces may provide similar capabilities for reading option files.

5.12. The MySQL Query Cache

From version 4.0.1 on, MySQL Server features a query cache. When in use, the query cache stores the text of a `SELECT` query together with the corresponding result that was sent to the client. If the identical query is received later, the server retrieves the results from the query cache rather than parsing and executing the query again.

The query cache is extremely useful in an environment where you have tables that don't change very often and for which the server receives a lot of identical queries. This is a typical situation for many Web servers that generate a lot of dynamic pages based on database content.

Note: The query cache does not return stale data. When tables are modified, any relevant entries in the query cache are flushed.

Note: The query cache does not work in an environment where you have many `mysqld` servers updating the same `MyISAM` tables.

Note: The query cache isn't used for server-side prepared statements. If you're using server-side prepared statements consider that these statement won't be satisfied by the query cache. See Section 23.2.4, "C API Prepared Statements".

Some performance data for the query cache follow. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2 x 500MHz system with 2GB RAM and a 64MB query cache.

- If all the queries you're performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.

- Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` system variable to 0. By disabling the query cache code, there is no noticeable overhead. Query cache capabilities can be excluded from the server entirely by using the `--without-query-cache` option to `configure` when compiling MySQL.

5.12.1. How the Query Cache Operates

This section describes how the query cache works when it is operational. Section 5.12.3, "Query Cache Configuration" describes how to control whether or not it is operational.

Queries are compared before parsing, so the following two queries are regarded as different by the query cache:

```
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be exactly the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

Before a query is fetched from the query cache, MySQL checks that the user has `SELECT` privilege for all the involved databases and tables. If this is not the case, the cached result is not used.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See Section 5.12.4, "Query Cache Status and Maintenance".

If a table changes, then all cached queries that use the table become invalid and are removed from the cache. This includes queries that use `MERGE` tables that map to the changed table. A table can be changed by many types of statements, such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, `ALTER TABLE`, `DROP TABLE`, or `DROP DATABASE`.

Transactional `InnoDB` tables that have been changed are invalidated when a `COMMIT` is performed.

In MySQL 4.0, the query cache is disabled within transactions (it does not return results). Beginning with MySQL 4.1.1, the query cache also works within transactions when using `InnoDB` tables (it uses the table version number to detect whether or not its contents are still current).

Before MySQL 5.0, a query that begins with a leading comment might be cached, but could not be fetched from the cache. This problem is fixed in MySQL 5.0.

The query cache works for `SELECT SQL_CALC_FOUND_ROWS ...` and `SELECT FOUND_ROWS()` type queries. `FOUND_ROWS()` returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache.

A query cannot be cached if it contains any of the following functions:

BENCHMARK()	CONNECTION_ID()	CURDATE()
CURRENT_DATE()	CURRENT_TIME()	CURRENT_TIMESTAMP()
CURTIME()	DATABASE()	ENCRYPT() with one parameter

FOUND_ROWS()	GET_LOCK()	LAST_INSERT_ID()
LOAD_FILE()	MASTER_POS_WAIT()	NOW()
RAND()	RELEASE_LOCK()	SLEEP()
SYSDATE()	UNIX_TIMESTAMP() with no parameters	USER()

A query also is not cached under these conditions:

- It refers to user-defined functions (UDFs).

- It refers to user variables.

- It refers to the tables in the `mysql` system database.

- It is of any of the following forms:

```
SELECT ... IN SHARE MODE
SELECT ... FOR UPDATE
SELECT ... INTO OUTFILE ...
SELECT ... INTO DUMPFILE ...
SELECT * FROM ... WHERE autoincrement_col IS NULL
```

  The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See Section 24.1.14.1, "How to Get the Value of an `AUTO_INCREMENT` Column in ODBC".

- It was issued as a prepared statement, even if no placeholders were employed. For example, the query used here:

```
char *my_sql_stmt = "SELECT a, b FROM table_c";
/* ... */
mysql_stmt_prepare(stmt, my_sql_stmt, strlen(my_sql_stmt));
```

  is not cached. See Section 23.2.4, "C API Prepared Statements".

- It uses `TEMPORARY` tables.

- It does not use any tables.

- The user has a column-level privilege for any of the involved tables.

5.12.2. Query Cache `SELECT` Options

Two query cache-related options may be specified in `SELECT` statements:

-
  `SQL_CACHE`

  The query result is cached if the value of the `query_cache_type` system variable is `ON` or `DEMAND`.

- `SQL_NO_CACHE`

  The query result is not cached.

Examples:

```
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

5.12.3. Query Cache Configuration

The `have_query_cache` server system variable indicates whether the query cache is available:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| have_query_cache | YES   |
+------------------+-------+
```

Several other system variables control query cache operation. These can be set in an option file or on the command line when starting `mysqld`. The query cache system variables all have names that begin with `query_cache_`. They are described briefly in Section 5.3.3, "Server System Variables", with additional configuration information given here.

To set the size of the query cache, set the `query_cache_size` system variable. Setting it to 0 disables the query cache. The default cache size is 0; that is, the query cache is disabled.

When setting `query_cache_size` to a non-zero value keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on architecture.) If you set the value too small, you'll get a warning, like in this example:

```
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
   Code: 1282
Message: Query cache failed to set size 39936; new query cache size is 0

mysql> SET GLOBAL query_cache_size = 41984;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| query_cache_size | 41984 |
+------------------+-------+
```

If the query cache size is greater than 0, the `query_cache_type` variable influences how it works. This variable can be set to the following values:

- A value of `0` or `OFF` prevents caching or retrieval of cached results.

- A value of `1` or `ON` allows caching except of those statements that begin with `SELECT SQL_NO_CACHE`.

- A value of `2` or `DEMAND` causes caching of only those statements that begin with `SELECT SQL_CACHE`.

Setting the `GLOBAL` value of `query_cache_type` determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the `SESSION` value of `query_cache_type`. For example, a client can disable use of the query cache for its own queries like this:

```
mysql> SET SESSION query_cache_type = OFF;
```

To control the maximum size of individual query results that can be cached, set the
`query_cache_limit` variable. The default value is 1MB.

The result of a query (the data sent to the client) is stored in the query cache during result retrieval.
Therefore the data usually is not handled in one big chunk. The query cache allocates blocks for
storing this data on demand, so when one block is filled, a new block is allocated. Because memory
allocation operation is costly (timewise), the query cache allocates blocks with a minimum size giv-
en by the `query_cache_min_res_unit` system variable. When a query is executed, the last
result block is trimmed to the actual data size so that unused memory is freed. Depending on the
types of queries your server executes, you might find it helpful to tune the value of
`query_cache_min_res_unit`:

- The default value of `query_cache_min_res_unit` is 4KB. This should be adequate for
  most cases.

- If you have a lot of queries with small results, the default block size may lead to memory frag-
  mentation, as indicated by a large number of free blocks. Fragmentation can force the query
  cache to prune (delete) queries from the cache due to lack of memory. In this case, you should
  decrease the value of `query_cache_min_res_unit`. The number of free blocks and quer-
  ies removed due to pruning are given by the values of the `Qcache_free_blocks` and
  `Qcache_lowmem_prunes` status variables.

- If most of your queries have large results (check the `Qcache_total_blocks` and
  `Qcache_queries_in_cache` status variables), you can increase performance by increasing
  `query_cache_min_res_unit`. However, be careful to not make it too large (see the previ-
  ous item).

`query_cache_min_res_unit` is present from MySQL 4.1.

5.12.4. Query Cache Status and Maintenance

You can check whether the query cache is present in your MySQL server using the following state-
ment:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| have_query_cache | YES   |
+------------------+-------+
```

You can defragment the query cache to better utilize its memory with the FLUSH QUERY CACHE
statement. The statement does not remove any queries from the cache.

The RESET QUERY CACHE statement removes all query results from the query cache. The
FLUSH TABLES statement also does this.

To monitor query cache performance, use SHOW STATUS to view the cache status variables:

```
mysql> SHOW STATUS LIKE 'Qcache%';
+-------------------------+--------+
| Variable_name           | Value  |
+-------------------------+--------+
| Qcache_free_blocks      | 36     |
| Qcache_free_memory      | 138488 |
| Qcache_hits             | 79570  |
| Qcache_inserts          | 27087  |
| Qcache_lowmem_prunes    | 3114   |
```

```
| Qcache_not_cached       | 22989  |
| Qcache_queries_in_cache | 415    |
| Qcache_total_blocks     | 912    |
+-------------------------+--------+
```

Descriptions of each of these variables are given in Section 5.3.4, "Server Status Variables". Some uses for them are described here.

The total number of SELECT queries is equal to:

```
  Com_select
+ Qcache_hits
+ queries with errors found by parser
```

The Com_select value is equal to:

```
  Qcache_inserts
+ Qcache_not_cached
+ queries with errors found during columns/rights check
```

The query cache uses variable-length blocks, so Qcache_total_blocks and Qcache_free_blocks may indicate query cache memory fragmentation. After FLUSH QUERY CACHE, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one block needs to be allocated.

The information provided by the Qcache_lowmem_prunes status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in Section 5.12.3, "Query Cache Configuration".

Chapter 6. Replication in MySQL

Replication capabilities allowing the databases on one MySQL server to be duplicated on another were introduced in MySQL 3.23.15. This chapter describes the various replication features provided by MySQL. It introduces replication concepts, shows how to set up replication servers, and serves as a reference to the available replication options. It also provides a list of frequently asked questions (with answers), and troubleshooting advice for solving problems.

For a description of the syntax of replication-related SQL statements, see Section 13.6, "Replication Statements".

We suggest that you visit our Web site at http://www.mysql.com frequently as well as check for revisions to this chapter. Replication is constantly being improved, and we update the manual regularly with the most current information.

6.1. Introduction to Replication

MySQL 3.23.15 and up features support for one-way replication. One server acts as the master, while one or more other servers act as slaves. The master server writes updates to its binary log files, and maintains an index of the files to keep track of log rotation. These logs serve as a record of updates to be sent to slave servers. When a slave server connects to the master server, it informs the master of its last position within the logs since the last successfully propagated update. The slave catches up any updates that have occurred since then, and then blocks and waits for the master to notify it of new updates.

A slave server can itself serve as a master if you want to set up chained replication servers.

Note that when you are using replication, all updates to the tables that are replicated should be performed on the master server. Otherwise, you must always be careful to avoid conflicts between updates that users make to tables on the master and updates that they make to tables on the slave.

One-way replication has benefits for robustness, speed, and system administration:

- Robustness is increased with a master/slave setup. In the event of problems with the master, you can switch to the slave as a backup.

- Better response time for clients can be achieved by splitting the load for processing client queries between the master and slave servers. `SELECT` queries may be sent to the slave to reduce the query processing load of the master. Statements that modify data should still be sent to the master so that the master and slave do not get out of sync. This load-balancing strategy is effective if non-updating queries dominate, but that is the normal case.

- Another benefit of using replication is that you can perform backups using a slave server without disturbing the master. The master continues to process updates while the backup is being made. See Section 5.8.1, "Database Backups".

6.2. Replication Implementation Overview

MySQL replication is based on the master server keeping track of all changes to your databases (updates, deletes, and so on) in the binary logs. Therefore, to use replication, you must enable binary logging on the master server. See Section 5.10.4, "The Binary Log".

Each slave server receives from the master the saved updates that the master has recorded in its binary log, so that the slave can execute the same updates on its copy of the data.

It is *extremely* important to realize that the binary log is simply a record starting from the fixed point in time at which you enable binary logging. Any slaves that you set up need copies of the databases on your master *as they existed at the moment you enabled binary logging on the master*. If you start

your slaves with databases that are not in the same state as those on the master when the binary log was started, your slaves are quite likely to fail.

One way to copy the master's data to the slave is to use the `LOAD DATA FROM MASTER` statement. Be aware that `LOAD DATA FROM MASTER` is available only as of MySQL 4.0.0 and currently works only if all the tables on the master are `MyISAM` type. Also, this statement acquires a global read lock, so no updates on the master are possible while the tables are being transferred to the slave. When we implement lock-free hot table backup, this global read lock will no longer be necessary.

Due to these limitations, we recommend that at this point you use `LOAD DATA FROM MASTER` only if the dataset on the master is relatively small, or if a prolonged read lock on the master is acceptable. While the actual speed of `LOAD DATA FROM MASTER` may vary from system to system, a good rule of thumb for how long it takes is 1 second per 1MB of data. This is a rough estimate, but you should find it fairly accurate if both master and slave are equivalent to 700MHz Pentium CPUs in performance and are connected through a 100Mbps network.

After the slave has been set up with a copy of the master's data, it connects to the master and waits for updates to process. If the master fails, or the slave loses connectivity with your master, the slave keeps trying to connect periodically until it is able to resume listening for updates. The retry interval is controlled by the `--master-connect-retry` option. The default is 60 seconds.

Each slave keeps track of where it left off. The master server has no knowledge of how many slaves there are or of which ones are up to date at any given time.

6.3. Replication Implementation Details

MySQL replication capabilities are implemented using three threads (one on the master server and two on the slave). When a `START SLAVE` is issued, the slave creates an I/O thread, which connects to the master and asks it to send the statements recorded in its binary logs. The master creates a thread to send the binary log contents to the slave. This thread can be identified as the `Binlog Dump` thread in the output of `SHOW PROCESSLIST` on the master. The slave I/O thread reads what the master `Binlog Dump` thread sends and copies this data to local files, known as *relay logs*, in the slave's data directory. The third thread is the SQL thread, which the slave creates in order to read the relay logs and to execute the updates they contain.

In the preceding description, there are three threads per slave. A master that has multiple slaves creates one thread for each slave that is currently connected slave; each slave has its own I/O and SQL threads.

For versions of MySQL before 4.0.2, replication involves only two threads (one on the master and one on the slave). The slave I/O and SQL threads are combined as a single thread, and no relay log files are used.

The advantage of using two slave threads is that statement reading and execution are separated into two independent tasks. The task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind and may take hours to catch up. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This allows the binary logs to be purged on the master, because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication.

The following example illustrates how the three threads show up in `SHOW PROCESSLIST`. The output format is that used by `SHOW PROCESSLIST` as of MySQL version 4.0.15, when the content of the `State` column was changed to be more meaningful compared to earlier versions.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 2
   User: root
   Host: localhost:32931
     db: NULL
Command: Binlog Dump
   Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
         be updated
   Info: NULL
```

Here, thread 2 is a replication thread for a connected slave. The information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur.

On the slave server, the output from SHOW PROCESSLIST looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 10
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 11
  State: Waiting for master to send event
   Info: NULL
*************************** 2. row ***************************
     Id: 11
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 11
  State: Has read all relay log; waiting for the slave I/O
         thread to update it
   Info: NULL
```

This information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that the SHOW PROCESSLIST was run, both threads were idle, waiting for further updates.

Note that the value in the Time column can show how late the slave is compared to the master. See Section 6.9, "Replication FAQ".

6.3.1. Replication Master Thread States

The following list shows the most common states you may see in the State column for the master's Binlog Dump thread. If you don't see any Binlog Dump threads on a master server, this means that replication is not running — that is, that no slaves are currently connected.

- Sending binlog event to slave

  Binary logs consist of *events*, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the slave.

- Finished reading one binlog; switching to next binlog

  The thread has finished reading a binary log file and is opening the next one to send to the slave.

- Has sent all binlog to slave; waiting for binlog to be updated

The thread has read all outstanding updates from the binary logs and sent them to the slave. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the master.

- `Waiting to finalize termination`

A very brief state that occurs as the thread is stopping.

6.3.2. Replication Slave I/O Thread States

The following list shows the most common states you see in the `State` column for a slave server I/O thread. Beginning with MySQL 4.1.1, this state also appears in the `Slave_IO_State` column displayed by the `SHOW SLAVE STATUS` statement. This means that you can get a good view of what is happening by using only `SHOW SLAVE STATUS`.

- `Connecting to master`

The thread is attempting to connect to the master.

- `Checking master version`

A state that occurs very briefly, immediately after the connection to the master is established.

- `Registering slave on master`

A state that occurs very briefly immediately after the connection to the master is established.

- `Requesting binlog dump`

A state that occurs very briefly, immediately after the connection to the master is established. The thread sends to the master a request for the contents of its binary logs, starting from the requested binary log filename and position.

- `Waiting to reconnect after a failed binlog dump request`

If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `--master-connect-retry` option.

- `Reconnecting after a failed binlog dump request`

The thread is trying to reconnect to the master.

- `Waiting for master to send event`

The thread has connected to the master and is waiting for binary log events to arrive. This can last for a long time if the master is idle. If the wait lasts for `slave_read_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and make an attempt to reconnect.

- `Queueing master event to the relay log`

The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- `Waiting to reconnect after a failed master event read`

An error occurred while reading (due to disconnection). The thread is sleeping for `master-connect-retry` seconds before attempting to reconnect.

- `Reconnecting after a failed master event read`

The thread is trying to reconnect to the master. When connection is established again, the state becomes `Waiting for master to send event`.

• `Waiting for the slave SQL thread to free enough relay log space`

You are using a non-zero `relay_log_space_limit` value, and the relay logs have grown until their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

• `Waiting for slave mutex on exit`

A state that occurs briefly as the thread is stopping.

6.3.3. Replication Slave SQL Thread States

The following list shows the most common states you may see in the `State` column for a slave server SQL thread:

• `Reading event from the relay log`

The thread has read an event from the relay log so that the event can be processed.

• `Has read all relay log; waiting for the slave I/O thread to update it`

The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

• `Waiting for slave mutex on exit`

A very brief state that occurs as the thread is stopping.

The `State` column for the I/O thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and is executing it.

6.3.4. Replication Relay and Status Files

By default, relay logs are named using filenames of the form *host_name*-relay-bin.*nnnnnn*, where *host_name* is the name of the slave server host and *nnnnnn* is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001` (`001` in MySQL 4.0 or older). The slave keeps track of relay logs currently in use in an index file. The default relay log index filename is *host_name*-`relay-bin.index`. By default, these files are created in the slave's data directory. The default filenames may be overridden with the `--relay-log` and `--relay-log-index` server options. See Section 6.8, "Replication Startup Options".

Relay logs have the same format as binary logs, and can be read using `mysqlbinlog`. A relay log is automatically deleted by the SQL thread as soon as it has executed all its events and no longer needs it). There is no explicit mechanism for deleting relay logs, because the SQL thread takes care of doing so. However, from MySQL 4.0.14, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

A new relay log is created under the following conditions:

• When the I/O thread starts for the first time after the slave server starts. (In MySQL 5.0, a new relay log is created each time the I/O thread starts, not just the first time.)

• When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.

(This creates a new relay log only as of MySQL 4.0.14.)

- When the size of the current relay log file becomes too large. The meaning of "too large" is determined as follows:

  - `max_relay_log_size`, if `max_relay_log_size` > 0

  - `max_binlog_size`, if `max_relay_log_size` = 0 or MySQL is older than 4.0.14

A slave replication server creates two additional small files in the data directory. These *status files* are named `master.info` and `relay-log.info` by default. They contain information like that shown in the output of the SHOW SLAVE STATUS statement (see Section 13.6.2, "SQL Statements for Controlling Slave Servers" for a description of this statement). As disk files, they survive a slave server's shutdown. The next time the slave starts up, it reads these files to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The `master.info` file is updated by the I/O thread. Before MySQL 4.1, the correspondence between the lines in the file and the columns displayed by SHOW SLAVE STATUS is as follows:

Line	Description
1	`Master_Log_File`
2	`Read_Master_Log_Pos`
3	`Master_Host`
4	`Master_User`
5	Password (not shown by SHOW SLAVE STATUS)
6	`Master_Port`
7	`Connect_Retry`

As of MySQL 4.1, the file includes a line count and information about SSL options:

Line	Description
1	Number of lines in the file
2	`Master_Log_File`
3	`Read_Master_Log_Pos`
4	`Master_Host`
5	`Master_User`
6	Password (not shown by SHOW SLAVE STATUS)
7	`Master_Port`
8	`Connect_Retry`
9	`Master_SSL_Allowed`
10	`Master_SSL_CA_File`
11	`Master_SSL_CA_Path`
12	`Master_SSL_Cert`
13	`Master_SSL_Cipher`
14	`Master_SSL_Key`

The `relay-log.info` file is updated by the SQL thread. The correspondence between the lines in the file and the columns displayed by SHOW SLAVE STATUS is shown here:

Line	Description
1	`Relay_Log_File`

2	`Relay_Log_Pos`
3	`Relay_Master_Log_File`
4	`Exec_Master_Log_Pos`

When you back up the slave's data, you should back up these two small files as well, along with the relay log files. They are needed to resume replication after you restore the slave's data. If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master server.

If your slave is subject to replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The directory location is specified using the `--slave-load-tmpdir` option. Its default value, if not specified, is the value of the `tmpdir` variable.

6.4. How to Set Up Replication

Here is a brief description of how to set up complete replication of your current MySQL server. It assumes that you want to replicate all databases on the master and have not previously configured replication. You need to shut down your master server briefly to complete the steps outlined here.

This procedure is written in terms of setting up a single slave, but you can use it to set up multiple slaves.

While this method is the most straightforward way to set up a slave, it is not the only one. For example, if you have a snapshot of the master's data, and the master has its server ID set and binary logging enabled, you can set up a slave without shutting down the master or even blocking updates to it. For more details, please see Section 6.9, "Replication FAQ".

If you want to administer a MySQL replication setup, we suggest that you read this entire chapter through and try all statements mentioned in Section 13.6.1, "SQL Statements for Controlling Master Servers" and Section 13.6.2, "SQL Statements for Controlling Slave Servers". You should also familiarize yourself with replication startup options described in Section 6.8, "Replication Startup Options".

Note that this procedure and some of the replication SQL statements in later sections refer to the `SUPER` privilege. Prior to MySQL 4.0.2, use the `PROCESS` privilege instead.

1. Make sure that you have a recent version of MySQL installed on the master and slaves, and that these versions are compatible according to the table shown in Section 6.5, "Replication Compatibility Between MySQL Versions".

    Please do not report bugs until you have verified that the problem is present in the latest MySQL release.

2. Set up an account on the master server that the slave server can use to connect. This account must be given the `REPLICATION SLAVE` privilege. If the account is used only for replication (which is recommended), you don't need to grant any additional privileges. (For informaiton about setting up user accounts and privileges, see Section 5.7, "MySQL User Account Management".)

    Suppose that your domain is `mydomain.com` and you want to create an account with a username of `repl` such that slave servers can use the account to access the master server from any host in your domain using a password of `slavepass`. To create the account, this use `GRANT` statement:

    ```
    mysql> GRANT REPLICATION SLAVE ON *.*
    ```

```
        -> TO 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
```

For MySQL versions older than 4.0.2, the REPLICATION SLAVE privilege does not exist. Grant the FILE privilege instead:

```
mysql> GRANT FILE ON *.*
        -> TO 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
```

If you plan to use the LOAD TABLE FROM MASTER or LOAD DATA FROM MASTER statements from the slave host, you need to grant this account additional privileges:

- Grant the account the SUPER and RELOAD global privileges.

- Grant the SELECT privilege for all tables that you want to load. Any master tables from which the account cannot SELECT are ignored by LOAD DATA FROM MASTER.

3. Flush all the tables and block write statements by executing a FLUSH TABLES WITH READ LOCK statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

For InnoDB tables, note the following: FLUSH TABLES WITH READ LOCK blocks COMMIT operations, too. (This is true as of MySQL version 4.0.20.) When you have acquired your global read lock, you can start a filesystem snapshot of your InnoDB tables. Internally (inside the InnoDB storage engine) the snapshot won't be consistent (because the InnoDB caches are not flushed), but there's no need to worry at all, because InnoDB will resolve this at startup, and consequently deliver a consistent result. This means that InnoDB will perform a crash recovery when started on this snapshot, but it will not be corrupted. If you want to have a consistent snapshot of your InnoDB tables, there's no way around taking down the MySQL server, though.

Leave running the client from which you issue the FLUSH TABLES statement so that the read lock remains in effect. (If you exit the client, the lock is released.) Then take a snapshot of the data on your master server.

The easiest way to create a snapshot is to use an archiving program to make a binary backup of the databases in your master's data directory. For example, use tar on Unix, or Power-Archiver, WinRAR, WinZip, or any similar software on Windows. To use tar to create an archive that includes all databases, change location into the master server's data directory, then execute this command:

```
shell> tar -cvf /tmp/mysql-snapshot.tar .
```

If you want the archive to include only a database called this_db, use this command instead:

```
shell> tar -cvf /tmp/mysql-snapshot.tar ./this_db
```

Then copy the archive file to the /tmp directory on the slave server host. On that machine, change location into the slave's data directory, and unpack the archive file using this command:

```
shell> tar -xvf /tmp/mysql-snapshot.tar
```

You may not want to replicate the mysql database if the slave server has a different set of user accounts from those that exist on the master. In this case, you should exclude it from the archive. You also need not include any log files in the archive, or the master.info or re-lay-log.info files.

While the read lock placed by FLUSH TABLES WITH READ LOCK is in effect, read the value of the current binary log name and offset on the master:

```
mysql > SHOW MASTER STATUS;
+---------------+----------+--------------+------------------+
| File          | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+---------------+----------+--------------+------------------+
| mysql-bin.003 | 73       | test         | manual,mysql     |
+---------------+----------+--------------+------------------+
```

The `File` column shows the name of the log, while `Position` shows the offset. In this example, the binary log value is `mysql-bin.003` and the offset is 73. Record the values. You need to use them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

After you have taken the snapshot and recorded the log name and offset, you can re-enable write activity on the master:

```
mysql> UNLOCK TABLES;
```

If you are using `InnoDB` tables, ideally you should use the `InnoDB Hot Backup` tool, which takes a consistent snapshot without acquiring any locks on the master server, and records the log name and offset corresponding to the snapshot to be later used on the slave. `Hot Backup` is an additional non-free (commercial) tool that is not included in the standard MySQL distribution. See the InnoDB Hot Backup home page at http://www.innodb.com/manual.php for detailed information.

Without the `Hot Backup` tool, the quickest way to take a binary snapshot of `InnoDB` tables is to shut down the master server and copy the `InnoDB` data files, log files, and table definition files (`.frm` files). To record the current log file name and offset, you should issue the following statements before you shut down the server:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Then record the log name and the offset from the output of SHOW MASTER STATUS as was shown earlier. After recording the log name and the offset, shut down the server *without* unlocking the tables to make sure that the server goes down with the snapshot corresponding to the current log file and offset:

```
shell> mysqladmin -u root shutdown
```

An alternative that works for both `MyISAM` and `InnoDB` tables is to take an SQL dump of the master instead of a binary copy as described in the preceding discussion. For this, you can use `mysqldump --master-data` on your master and later load the SQL dump file into your slave. However, this is slower than doing a binary copy.

If the master has been previously running without `--log-bin` enabled, the log name and position values displayed by SHOW MASTER STATUS or `mysqldump --master-data` are empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (`' '`) and 4.

4. Make sure that the `[mysqld]` section of the `my.cnf` file on the master host includes a `log-bin` option. The section should also have a `server-id=master_id` option, where `master_id` must be a positive integer value from 1 to $2^{32} - 1$. For example:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

If those options are not present, add them and restart the server.

5. Stop the server that is to be used as a slave server and add the following to its `my.cnf` file:

```
[mysqld]
server-id=slave_id
```

The `slave_id` value, like the `master_id` value, must be a positive integer value from 1 to $2^{32} - 1$. In addition, it is very important that the ID of the slave be different from the ID of the master. For example:

```
[mysqld]
server-id=2
```

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

If you do not specify a `server-id` value, it is set to 1 if you have not defined `master-host`; otherwise it is set to 2. Note that in the case of `server-id` omission, a master refuses connections from all slaves, and a slave refuses to connect to a master. Thus, omitting `server-id` is good only for backup with a binary log.

6. If you made a binary backup of the master server's data, copy it to the slave server's data directory before starting the slave. Make sure that the privileges on the files and directories are correct. The user that the server MySQL runs as must able to read and write the files, just as on the master.

If you made a backup using `mysqldump`, start the slave first (see next step).

7. Start the slave server. If it has been replicating previously, start the slave server with the `--skip-slave-start` option so that it doesn't immediately try to connect to its master. You also may want to start the slave server with the `--log-warnings` option (enabled by default as of MySQL 4.0.19 and 4.1.2), to get more messages in the error log about problems (for example, network or connection problems). As of MySQL 4.0.21 and 4.1.3, aborted connections are not logged to the error log unless the value is greater than 1.

8. If you made a backup of the master server's data using `mysqldump`, load the dump file into the slave server:

```
shell> mysql -u root -p < dump_file.sql
```

9. Execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
    ->      MASTER_HOST='master_host_name',
    ->      MASTER_USER='replication_user_name',
    ->      MASTER_PASSWORD='replication_password',
    ->      MASTER_LOG_FILE='recorded_log_file_name',
    ->      MASTER_LOG_POS=recorded_log_position;
```

The following table shows the maximum length for the string options:

MASTER_HOST	60
MASTER_USER	16
MASTER_PASSWORD	32
MASTER_LOG_FILE	255

10. Start the slave threads:

    ```
    mysql> START SLAVE;
    ```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` value for the master, slaves are not able to connect to it.

If you have forgotten to set the `server-id` value for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host is set;
we will force server id to 2, but this MySQL server will not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement.

Note: The content of `master.info` overrides some of the options specified on the command line or in `my.cnf`. See Section 6.8, "Replication Startup Options" for more details.

Once you have a snapshot, you can use it to set up other slaves by following the slave portion of the procedure just described. You do not need to take another snapshot of the master; you can use the same one for each slave.

Note: For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions you should use `innodb_flush_logs_at_trx_commit=1`, `sync-binlog=1`, and `innodb_safe_binlog` in your master `my.cnf` file.

6.5.   Replication   Compatibility   Between MySQL Versions

The original binary log format was developed in MySQL 3.23. It changed in MySQL 4.0, and again in MySQL 5.0.0. The binary log format as implemented in MySQL 5.0 is considerably different than that used in previous versions. Major changes were made in MySQL 5.0.3 (for improvements to handling of character sets and `LOAD DATA INFILE`) and 5.0.4 (for improvements to handling of time zones).

Note: You cannot replicate from a master that uses a newer binary log format to a slave that uses an older format (for example, from MySQL 5.0 to MySQL 4.1.) This has significant consequences for upgrading servers in a replication setup, as described in Section 6.6, "Upgrading a Replication Setup".

As far as replication is concerned, the binary log format for any MySQL 4.1.x version and any 4.0.x version is identical. However, replication from a 4.1 master to a 4.0 slave is unsupported, has not been tested thoroughly, and no further development or bug fixing is planned for this master/slave combination. Although the binary log format is the same for 4.0 and 4.1, there are other constraints, such as SQL-level compatibility issues. For example, a 4.1 master cannot replicate to a 4.0 slave if the replicated statements use SQL features available in 4.1 but not 4.0. These and other issues are discussed in Section 6.7, "Replication Features and Known Problems".

We recommend using the most recent MySQL version available because replication capabilities are continually being improved. We also recommend using the same version for both the master and the

slave. We recommend upgrading masters and slaves running alpha or beta versions to new (production) versions. Replication from a 5.0.3 master to a 5.0.2 slave will fail; from a 5.0.4 master to a 5.0.3 slave will also fail. In general, slaves running MySQL 5.0.x can be used with older masters (even those running MySQL 3.23, 4.0, or 4.1), but not the reverse.

6.6. Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

6.6.1. Upgrading Replication to 4.0 or 4.1

This section applies to upgrading replication from MySQL 3.23 to 4.0 or 4.1. A 4.0 server should be 4.0.3 or newer, as mentioned in Section 6.5, "Replication Compatibility Between MySQL Versions".

When you upgrade a master from MySQL 3.23 to MySQL 4.0 or 4.1, you should first ensure that all the slaves of this master are at 4.0 or 4.1. If that is not the case, you should first upgrade your slaves: Shut down each one, upgrade it, restart it, and restart replication.

The upgrade can safely be done using the following procedure, assuming that you have a 3.23 master to upgrade and the slaves are 4.0 or 4.1. Note that after the master has been upgraded, you should not restart replication using any old 3.23 binary logs, because this unfortunately confuses the 4.0 or 4.1 slaves.

1. Block all updates on the master by issuing a `FLUSH TABLES WITH READ LOCK` statement.

2. Wait until all the slaves have caught up with all changes from the master server. Use `SHOW MASTER STATUS` on the master to obtain its current binary log file and position. Then, for each slave, use those values with a `SELECT MASTER_POS_WAIT()` statement. The statement blocks on the slave and returns when the slave has caught up. Then run `STOP SLAVE` on the slave.

3. Stop the master server and upgrade it to MySQL 4.0 or 4.1.

4. Restart the master server and record the name of its newly created binary log. You can obtain the name of the file by issuing a `SHOW MASTER STATUS` statement on the master. Then issue these statements on each slave:

```
mysql> CHANGE MASTER TO MASTER_LOG_FILE='binary_log_name',
    ->     MASTER_LOG_POS=4;
mysql> START SLAVE;
```

6.6.2. Upgrading Replication to 5.0

This section applies to upgrading replication from MySQL 3.23, 4.0, or 4.1 to 5.0. A 4.0 server should be 4.0.3 or newer.

First, note that MySQL 5.0.0 is an alpha release. It is intended to work better than older versions (easier upgrade, replication of some important session variables such as `sql_mode`; see Section E.1.14, "Changes in release 5.0.0 (22 Dec 2003: Alpha)"). However it has not yet been extensively tested. As with any alpha release, we recommend that you not use it in critical production environments yet.

When you upgrade a master from MySQL 3.23, 4.0, or 4.1 to 5.0.0, you should first ensure that all the slaves of this master are using the same 5.0.x release. If this is not the case, you should first upgrade your slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.0.x version,

restart it, and restart replication. The 5.0 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.0 format.

After the slaves have been upgraded, shut down your master, upgrade it to the same 5.0.x release as the slaves, and restart it. The 5.0 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.0 slaves. The slaves recognize the old format and handle it properly. Binary logs created by master following the upgrade are in 5.0 format. These too are recognized by the 5.0 slaves.

In other words, there are no measures to take when upgrading to 5.0, except that the slaves must be 5.0 before you can upgrade the master to 5.0. Note that downgrading from 5.0 to older versions does not work so simply: you must ensure that any 5.0 binary logs or relay logs have been fully processed, so that you can remove them before proceeding with the downgrade.

6.7. Replication Features and Known Problems

In general, replication compatibility at the SQL level requires that any features used be supported by both the master and the slave servers. For example, the `GROUP_CONCAT()` function is available in MySQL 4.1 and up. If you use this function on the master server, you cannot replicate to a slave server that is older than MySQL 4.1.

The following list provides details about what is supported and what is not. Additional `InnoDB`-specific information about replication is given in Section 15.7.5, "`InnoDB` and MySQL Replication".

Replication issues with regard to stored routines and triggers is described in Section 18.4, "Binary Logging of Stored Routines and Triggers".

- Replication is done correctly with `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values.

- The `USER()`, `UUID()`, and `LOAD_FILE()` functions are replicated without changes and thus do not work reliably on the slave. This is also true for `CONNECTION_ID()` in slave versions older than 4.1.1. The **new** `PASSWORD()` function in MySQL 4.1 is well replicated in masters from 4.1.1 and up; your slaves also must be 4.1.1 or above to replicate it. If you have older slaves and need to replicate `PASSWORD()` from your 4.1.x master, you must start your master with the `--old-password` option, so that it uses the old implementation of `PASSWORD()`. (Note that the `PASSWORD()` implementation in MySQL 4.1.0 differs from every other version of MySQL. It is best to avoid 4.1.0 in a replication scenario.)

- *The following restriction applies to statement-based replication only, not to row-based replication.* The functions handling user-level locks: `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()` are replicated without the slave knowing the concurrency context on master; so these functions should not be used to insert into a master's table as the content on slave would differ (i.e. do not do `INSERT INTO mytable VALUES(GET_LOCK(...))`).

- The `FOREIGN_KEY_CHECKS` variable is replicated as of MySQL 4.0.14. The `SQL_MODE`, `UNIQUE_CHECKS`, and `SQL_AUTO_IS_NULL` variables are all replicated in MySQL 5.0. The `TABLE_TYPE`, also known as `STORAGE_ENGINE` variable is not yet replicated, which is a good thing for replication between different storage engines.

- Starting from MySQL 5.0.3 (master and slave), replication works fine even if the master and slave have different global character set variables. Starting from MySQL 5.0.4 (master and slave), replication works fine even if the master and slave have different global timezone variables.

- The following applies to replication between MySQL servers using different character sets:

1. You must **always** use the same **global** character set and collation (--default-character-set, --default-collation) on the master and the slave. Otherwise, you may get duplicate-key errors on the slave, because a key that is regarded as unique in the master's character set may not be unique in the slave's character set.

2. If the master is older than MySQL 4.1.3, then the character set of the session should never be made different from its global value (in other words, do not use SET NAMES, SET CHARACTER SET, and so on) because this character set change is not known to the slave. If both the master and the slave are 4.1.3 or newer, the session can freely set local values for character set variables (such as NAMES, CHARACTER SET, COLLATION_CLIENT, and COLLATION_SERVER) as these settings are written to the binary log and so known to the slave. However, the session is prevented from changing the **global** value of these; as stated previously, the master and slave must always have identical global character set values.

3.
   If on the master you have databases with different character sets from the global collation_server value, you should design your CREATE TABLE statements so that they do not implicitly rely on the default database's character set, because there currently is a bug (Bug #2326 [http://bugs.mysql.com/2326]); a good workaround is to state the character set and collation explicitly in CREATE TABLE.

- For both master and slave the same system time zone should be set. Otherwise some statements, for example statements using NOW() or FROM_UNIXTIME() functions, won't be replicated properly. One could set the time zone in which MySQL server runs by using the --timezone=*timezone_name* option of the mysqld_safe script or by setting the TZ environment variable. Both master and slave should also have the same default connection time zone setting; that is, the --default-time-zone parameter should have the same value for both master and slave.

- CONVERT_TZ(...,...,@global.time_zone) is not properly replicated. CONVERT_TZ(...,...,@session.time_zone) is properly replicated only if master and slave are 5.0.4 or newer.

- Session variables are not replicated properly when used in statements which update tables; for example: SET MAX_JOIN_SIZE=1000; INSERT INTO mytable VALUES(@MAX_JOIN_SIZE); will not insert the same data on master and on slave. This does not apply to the common SET TIME_ZONE=...; INSERT INTO mytable VALUES(CONVERT_TZ(...,...,@time_zone)), which is fixed in MySQL 5.0.4.

-
   It is possible to replicate transactional tables on the master using non-transactional tables on the slave. For example, you can replicate an InnoDB master table as a MyISAM slave table. However, if you do this, there are problems if the slave is stopped in the middle of a BEGIN/COMMIT block, because the slave restarts at the beginning of the BEGIN block. This issue is on our TODO and will be fixed in the near future.

- Update statements that refer to user variables (that is, variables of the form @*var_name*) are badly replicated in 3.23 and 4.0. This is fixed in 4.1. Note that user variable names are case insensitive starting from MySQL 5.0. You should take this into account when setting up replication between 5.0 and an older version.

- The slave can connect to the master using SSL if both are 4.1.1 or newer.

- Starting from MySQL 4.1.11 and 5.0.3, there is a global system variable slave_transaction_retries: If the replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or exceeded InnoDB's innodb_lock_wait_timeout or NDBCluster's TransactionDeadlockDetectionTimeout or TransactionInactiveTimeout, it automatically retries slave_transaction_retries times before stopping with an error. The default value is 0 in MySQL 4.1 and 10 in MySQL 5.0. Starting from MySQL 4.1.11 and 5.0.4, the total count of retries can be seen in SHOW STATUS, see Section 5.3.4, "Server Status Variables".

- If a `DATA DIRECTORY` or `INDEX DIRECTORY` clause is used in a `CREATE TABLE` statement on the master server, the clause is also used on the slave. This can cause problems if no corresponding directory exists in the slave host filesystem or exists but is not accessible to the slave server. Starting from MySQL 4.0.15, there is a `sql_mode` option called `NO_DIR_IN_CREATE`. If the slave server is run with its SQL mode set to include this option, it ignores the clauses before replicating the `CREATE TABLE` statement. The result is that the `My-ISAM` data and index files are created in the table's database directory.

- *The following restriction applies to statement-based replication only, not to row-based replication*: It is possible for the data on the master and slave to become different if a query is designed in such a way that the data modification is non-deterministic; that is, left to the will of the query optimizer. (This is in general not a good practice, even outside of replication.) For a detailed explanation of this issue, see Section A.8.4, "Open Issues in MySQL".

- The following paragraph is no longer true if master and slave are both running MySQL version 5.0.4 or newer. If on master a `LOAD DATA INFILE` is interrupted in the middle (integrity constraint violation, killed connection...), the slave skips this `LOAD DATA INFILE` entirely. It means that if this command permanently inserted/updated some table records before being interrupted, these modifications won't be replicated to the slave.

- Before MySQL 4.1.1, `FLUSH`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are not written to the binary log and thus are not replicated to the slaves. This is not normally a problem because these statements do not modify table data. However, it can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using the `GRANT` statement, you must issue a `FLUSH PRIVILEGES` statement on your slaves to put the new privileges into effect. Also if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you have to issue `FLUSH TABLES` manually on the slaves. As of MySQL 4.1.1, these statements are written to the binary log (unless you specify `NO_WRITE_TO_BINLOG`, or its alias `LOCAL`). Exceptions are that `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK` are not logged in any case. (Any of these may cause problems if replicated to a slave.) For a syntax example, see Section 13.5.5.2, "`FLUSH` Syntax".

- MySQL only supports one master and many slaves. Later we will add a voting algorithm to automatically change master if something goes wrong with the current master. We will also introduce "agent" processes to help do load balancing by sending `SELECT` queries to different slaves.

- When a server shuts down and restarts, its `MEMORY (HEAP)` tables become empty. In MySQL 5.0, the master replicates this effect as follows: The first time that the master uses each `MEMORY` table after startup, it notifies the slaves that the table needs to be emptied by writing a `DELETE FROM` statement for that table to the binary log. See Section 14.3, "The `MEMORY (HEAP)` Storage Engine" for more information.

- Temporary tables are replicated except in the case where you shut down the slave server (not just the slave threads) and you have replicated temporary tables that are used in updates that have not yet been executed on the slave. If you shut down the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

  1. Issue a `STOP SLAVE` statement.

  2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.

  3. If the value is 0, issue a `mysqladmin shutdown` command to shut down the slave.

  4. If the value is not 0, restart the slave threads with `START SLAVE`.

  5. Repeat the procedure later to see if you have better luck next time.

  We plan to fix this problem in the near future.

- It is safe to connect servers in a circular master/slave relationship with the `--log-slave-updates` option specified. Note, however, that many statements do not work correctly in this kind of setup unless your client code is written to take care of the potential problems that can occur from updates that occur in different sequence on different servers.

  This means that you can create a setup such as this:

  ```
  A -> B -> C -> A
  ```

  Server IDs are encoded in binary log events, so server A knows when an event that it reads was originally created by itself and does not execute the event (unless server A was started with the `--replicate-same-server-id` option, which is meaningful only in rare cases). Thus, there are no infinite loops. This type of circular setup works only if you perform no conflicting updates between the tables. In other words, if you insert data in both A and C, you should never insert a row in A that may have a key that conflicts with a row inserted in C. You should also not update the same rows on two servers if the order in which the updates are applied is significant.

- If a statement on the slave produces an error, the slave SQL thread terminates, and the slave writes a message to its error log. You should then connect to the slave manually, fix the problem (for example, a non-existent table), and then run `START SLAVE`.

- It is safe to shut down a master server and restart it later. If a slave loses its connection to the master, the slave tries to reconnect immediately. If that fails, the slave retries periodically. (The default is to retry every 60 seconds. This may be changed with the `--master-connect-retry` option.) The slave also is able to deal with network connectivity outages. However, the slave does notice the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 5.3.3, "Server System Variables".

- Shutting down the slave (cleanly) is also safe, as it keeps track of where it left off. Unclean shutdowns might produce problems, especially if disk cache was not flushed to disk before the system went down. Your system fault tolerance is greatly increased if you have a good uninterruptible power supply. Unclean shutdowns of the master may cause inconsistencies between the content of tables and the binary log in master; this can be avoided by using `InnoDB` tables and the `--innodb-safe-binlog` option on the master. See Section 5.10.4, "The Binary Log".

- Due to the non-transactional nature of `MyISAM` tables, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave thread exits and waits for the database administrator to decide what to do about it unless the error code is legitimate and the statement execution results in the same error code. If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option. This option is available starting with MySQL 3.23.47.

- If you update transactional tables from non-transactional tables inside a `BEGIN/COMMIT` sequence, updates to the binary log may be out of sync if the non-transactional table is updated before the transaction commits. This is because the transaction is written to the binary log only when it is committed.

- Before version 4.0.15, any update to a non-transactional table is written to the binary log at once when the update is made, whereas transactional updates are written on `COMMIT` or not written at all if you use `ROLLBACK`. You must take this into account when updating both transactional tables and non-transactional tables within the same transaction. (This is true not only for replication, but also if you are using binary logging for backups.) In version 4.0.15, we changed the logging behavior for transactions that mix updates to transactional and non-transactional tables, which solves the problems (order of statements is good in the binary log, and all needed statements are written to the binary log even in case of `ROLLBACK`). The problem that remains is when a second connection updates the non-transactional table while the first connection's transaction is not finished yet; wrong order can still occur, because the second connection's update is written immediately after it is done.

- When a 4.x slave replicates a `LOAD DATA INFILE` from a 3.23 master, the values of the `Exec_Master_Log_Pos` and `Relay_Log_Space` columns of `SHOW SLAVE STATUS` become incorrect. The inaccuracy in `Exec_Master_Log_Pos` causes problems when you stop and restart replication; so it is a good idea to correct the value before this, by doing `FLUSH LOGS` on the master. These bugs are fixed in MySQL 5.0.0 slaves.

The following table lists replication problems in MySQL 3.23 that are fixed in MySQL 4.0:

- `LOAD DATA INFILE` is handled properly, as long as the data file still resides on the master server at the time of update propagation.

- `LOAD DATA LOCAL INFILE` is no longer skipped on the slave as it was in 3.23.

- In 3.23, `RAND()` in updates does not replicate properly. Use `RAND(some_non_rand_expr)` if you are replicating updates with `RAND()`. You can, for example, use `UNIX_TIMESTAMP()` as the argument to `RAND()`.

6.8. Replication Startup Options

On both the master and the slave, you must use the `server-id` option to establish a unique replication ID for each server. You should pick a unique positive integer in the range from 1 to $2^{32} - 1$ for each master and slave. Example: `server-id=3`

The options that you can use on the master server for controlling binary logging are described in Section 5.10.4, "The Binary Log".

The following table describes the options you can use on slave replication servers. You can specify them on the command line or in an option file.

Some slave server replication options are handled in a special way, in the sense that they are ignored if a `master.info` file exists when the slave starts and contains values for the options. The following options are handled this way:

- `--master-host`

- `--master-user`

- `--master-password`

- `--master-port`

- `--master-connect-retry`

As of MySQL 4.1.1, the following options also are handled specially:

- `--master-ssl`

- `--master-ssl-ca`

- `--master-ssl-capath`

- `--master-ssl-cert`

- `--master-ssl-cipher`

- `--master-ssl-key`

The `master.info` file format in 4.1.1 changed to include values corresponding to the SSL options. In addition, the 4.1.1 file format includes as its first line the number of lines in the file. If you upgrade an older server to 4.1.1, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a 4.1.1 or newer server to a version older than 4.1.1, you should manually remove the first line before starting the older server for the first time. Note that, in this case, the downgraded server no longer can use an SSL connection to communicate with the master.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

If the `master.info` file exists when the slave server starts, the server ignores those options. Instead, it uses the values found in the `master.info` file.

If you restart the slave server with different values of the startup options that correspond to values in the `master.info` file, the different values have no effect, because the server continues to use the `master.info` file. To use different values, you must either restart after removing the `master.info` file or (preferably) use the `CHANGE MASTER TO` statement to reset the values while the slave is running.

Suppose that you specify this option in your `my.cnf` file:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host of `some_other_host`, the change still has no effect. You should use `CHANGE MASTER TO` instead.

Because the server gives an existing `master.info` file precedence over the startup options just described, you might prefer not to use startup options for these values at all, and instead specify them by using the `CHANGE MASTER TO` statement. See Section 13.6.2.1, "CHANGE MASTER TO Syntax".

This example shows a more extensive use of startup options to configure a slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

The following list describes startup options for controlling replication: Many of these options can be reset while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. We plan to fix this.

- `--log-slave-updates`

    Normally, updates received from a master server by a slave are not logged to its binary log. This option tells the slave to log the updates performed by its SQL thread to the slave's own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want a setup like this:

```
A -> B -> C
```

That is, A serves as the master for the slave B, and B serves as the master for the slave C. For this to work, B must be both a master *and* a slave. You must start both A and B with --log-bin to enable binary logging, and B with the `--log-slave-updates` option.

- `--log-warnings`

Makes the slave print more messages to the error log about what it is doing. For example, it warns you that it succeeded in reconnecting after a network/connection failure, and warns you about how each slave thread started. This option is enabled by default as of MySQL 4.0.19 and 4.1.2; to disable it, use `--skip-log-warnings`. As of MySQL 4.0.21 and 4.1.3, aborted connections are not logged to the error log unless the value is greater than 1.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-connect-retry=seconds`

The number of seconds the slave thread sleeps before retrying to connect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60.

- `--master-host=host`

The hostname or IP number of the master replication server. If this option is not given, the slave thread does not start. The value in `master.info` takes precedence if it can be read.

- `--master-info-file=file_name`

The name to use for the file in which the slave records information about the master. The default name is `mysql.info` in the data directory.

- `--master-password=password`

The password of the account that the slave thread uses for authentication when connecting to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

- `--master-port=port_number`

The TCP/IP port the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed. If you have not tinkered with `configure` options, this should be 3306.

- `--master-ssl` , `--master-ssl-ca=file_name` , `--master-ssl-capath=directory_name` , `--master-ssl-cert=file_name` , `--master-ssl-cipher=cipher_list` , `--master-ssl-key=file_name`

These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl`, `--ssl-ca`, `--ssl-capath`, `--ssl-cert`, `--ssl-cipher`, `--ssl-key` options described in Section 5.7.7.6, "SSL Command-Line Options". The values in the `master.info` file take precedence if they can be read.

These options are operational as of MySQL 4.1.1.

- `--master-user=username`

The username of the account that the slave thread uses for authentication when connecting to the master. The account must have the `REPLICATION SLAVE` privilege. (Prior to MySQL 4.0.2, it must have the `FILE` privilege instead.) The value in the `master.info` file takes precedence

if it can be read. If the master user is not set, user `test` is assumed.

- `--max-relay-log-size=size`

  To rotate the relay log automatically. See Section 5.3.3, "Server System Variables".

  This option is available as of MySQL 4.0.14.

- `--read-only`

  This option causes the slave to allow no updates except from slave threads or from users with the `SUPER` privilege. This can be useful to ensure that a slave server accepts no updates from clients.

  This option is available as of MySQL 4.0.14.

- `--relay-log=file_name`

  The name for the relay log. The default name is `host_name-relay-bin.nnnnnn`, where `host_name` is the name of the slave server host and `nnnnnn` indicates that relay logs are created in numbered sequence. You can specify the option to create hostname-independent relay log names, or if your relay logs tend to be big (and you don't want to decrease `max_relay_log_size`) and you need to put them in some area different from the data directory, or if you want to increase speed by balancing load between disks.

- `--relay-log-index=file_name`

  The location and name that should be used for the relay log index file. The default name is `host_name-relay-bin.index`, where `host_name` is the name of the slave server.

- `--relay-log-info-file=file_name`

  The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `--relay-log-purge={0|1}`

  Disables or enables automatic purging of relay logs as soon as they are not needed any more. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge`.

  This option is available as of MySQL 4.1.1.

- `--relay-log-space-limit=size`

  Places an upper limit on the total size of all relay logs on the slave (a value of 0 means "unlimited"). This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs. Not doing so would cause a deadlock (which is what happens before MySQL 4.0.13). You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to temporarily ignore `--relay-log-space-limit`.

- `--replicate-do-db=db_name`

  Tells the slave to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database. Note that this does not replicate cross-database statements such as UP-

DATE *some_db.some_table* SET foo='bar' while having selected a different database or no database. If you need cross-database updates to work, make sure that you have MySQL 3.23.28 or later, and use --replicate-wild-do-table=*db_name*.%. Please read the notes that follow this option list.

An example of what does not work as you might expect: If the slave is started with --replicate-do-db=sales and you issue the following statements on the master, the UP-DATE statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

If you need cross-database updates to work, use --replicate-wild-do-table=*db_name*.% instead.

The main reason for this "check-just-the-default-database" behavior is that it's difficult from the statement alone to know whether or not it should be replicated (for example, if you are using multiple-table DELETE or multiple-table UPDATE statements that go across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

- --replicate-do-table=*db_name.tbl_name*

Tells the slave thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates, in contrast to --replicate-do-db. Please read the notes that follow this option list.

- --replicate-ignore-db=*db_name*

Tells the slave to not replicate any statement where the default database (that is, the one selected by USE) is *db_name*. To specify more than one database to ignore, use this option multiple times, once for each database. You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. Please read the notes that follow this option list.

An example of what does not work as you might expect: If the slave is started with --replicate-ignore-db=sales and you issue the following statements on the master, the UPDATE statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

If you need cross-database updates to work, use --replicate-wild-ignore-table=*db_name*.% instead.

- --replicate-ignore-table=*db_name.tbl_name*

Tells the slave thread to not replicate any statement that updates the specified table (even if any other tables might be updated by the same statement). To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to --replicate-ignore-db. Please read the notes that follow this option list.

- --replicate-wild-do-table=*db_name.tbl_name*

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the '%' and '_' wildcard characters, which have the same meaning as for the LIKE pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. Please read the notes that follow this option list.

Example: --replicate-wild-do-table=foo%.bar% replicates only updates that use a table where the database name starts with foo and the table name starts with bar.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the '_' and '%' characters like this: `--replicate-wild-do-table=my\_own\%db`. If you're using the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

  Tells the slave thread to not replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. Please read the notes that follow this option list.

  Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

  For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--replicate-rewrite-db=from_name->to_name`

  Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` was the default database on the master. This does not work for cross-database updates. Note that the database name translation is done before `--replicate-*` rules are tested.

  If you use this option on the command line and the '>' character is special to your command interpreter, quote the option value. For example:

  ```
  shell> mysqld --replicate-rewrite-db="olddb->newdb"
  ```

- `--replicate-same-server-id`

  To be used on slave servers. Usually you can should the default setting of 0, to prevent infinite loops in circular replication. If set to 1, this slave does not skip events having its own server id; normally this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. Be careful that starting from MySQL 4.1, by default the slave I/O thread does not even write binary log events to the relay log if they have the slave's server id (this optimization helps save disk usage compared to 4.0). So if you want to use `--replicate-same-server-id` in 4.1 versions, be sure to start the slave with this option before you make the slave read its own events which you want the slave SQL thread to execute.

- `--report-host=slave_name`

  The hostname or IP number of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP number of the slave from the TCP/IP socket after the slave connects. Due to `NAT` and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

  This option is available as of MySQL 4.0.0.

- `--report-port=slave_port`

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set it only if the slave is listening on a non-default port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, leave this option unset.

This option is available as of MySQL 4.0.0.

- `--skip-slave-start`

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it.

- `--slave-load-tmpdir=file_name`

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the to-be-loaded file from the relay log into temporary files, then loads these into the table. If the file loaded on the master was huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some filesystem that has a lot of available space. In that case, you may also use the `--relay-log` option to place the relay logs in that filesystem, because the relay logs are huge as well. `--slave-load-tmpdir` should point to a disk-based filesystem, not a memory-based one: The slave needs the temporary files used to replicate `LOAD DATA INFILE` to survive a machine's restart. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

The number of seconds to wait for more data from the master before aborting the read, considering the connection broken, and trying to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `--master-connect-retry` option.

- `--slave-skip-errors=[err_code1,err_code2,... | all]`

Normally, replication stops when an error occurs, which gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of sync with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. The server error codes are listed in Appendix B, *Error Codes and Messages*.

You can also (but should not) use the very non-recommended value of `all` which ignores all error messages and keeps going regardless of what happens. Needless to say, if you use it, we make no guarantees regarding integrity the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

The slave server evaluates the `--replicate-*` rules as follows to determine whether to execute or ignore a statement:

1. Are there any `--replicate-do-db` or `--replicate-ignore-db` rules?

   - *Yes*: Test them as for `--binlog-do-db` and `--binlog-ignore-db` (see Section 5.10.4, "The Binary Log"). What is the result of the test?

     - An "ignore" rule matched: Ignore the statement and exit.

     - A "do" rule matched: Do not execute the statement immediately; defer the decision; proceed to the next step.

   - *No*: Proceed to the next step.

2. Are we currently executing a stored procedure or function?

   - *Yes*: Execute the query and exit.

   - *No*: Proceed to the next step.

3. Are there any `--replicate-*-table` rules?

   - *No*: Execute the query and exit.

   - *Yes*: Proceed to the next step and begin evaluating the table rules in the order shown (first the non-wild rules, and then the wild rules). Only tables that are to be updated are compared to the rules (`INSERT INTO sales SELECT * FROM prices`: only `sales` is compared to the rules). If several tables are to be updated (multiple-table statement), the first matching table (matching "do" or "ignore") wins. That is, the first table is compared to the rules. Then, if no decision could be made, the second table is compared to the rules, and so on.

4. Are there any `--replicate-do-table` rules?

   - *Yes*: Does the table match any of them?

     - *Yes*: Execute the query and exit.

     - *No*: Proceed to the next step.

   - *No*: Proceed to the next step.

5. Are there any `--replicate-ignore-table` rules?

   - *Yes*: Does the table match any of them?

     - *Yes*: Ignore the query and exit.

     - *No*: Proceed to the next step.

   - *No*: Proceed to the next step.

6. Are there any `--replicate-wild-do-table` rules?

   - *Yes*: Does the table match any of them?

     - *Yes*: Execute the query and exit.

     - *No*: Proceed to the next step.

   - *No*: Proceed to the next step.

7. Are there any `--replicate-wild-ignore-table` rules?

- *Yes*: Does the table match any of them?

  - *Yes*: Ignore the query and exit.

  - *No*: Proceed to the next step.

- *No*: Proceed to the next step.

8. No `--replicate-*-table` rule was matched. Is there another table to test against these rules?

- *Yes*: Loop.

- *No*: We have now tested all tables to be updated and could not match any rule. Are there `--replicate-do-table` or `--replicate-wild-do-table` rules?

  - *Yes*: There were "do" rules but no match. Ignore the query and exit.

  - *No*: Execute the query and exit.

6.9. Replication FAQ

Q: How do I configure a slave if the master is running and I do not want to stop it?

A: There are several options. If you have taken a backup of the master at some point and recorded the binary log name and offset (from the output of SHOW MASTER STATUS) corresponding to the snapshot, use the following procedure:

1. Make sure that the slave is assigned a unique server ID.

2. Execute the following statement on the slave, filling in appropriate values for each option:

```
mysql> CHANGE MASTER TO
    ->     MASTER_HOST='master_host_name',
    ->     MASTER_USER='master_user_name',
    ->     MASTER_PASSWORD='master_pass',
    ->     MASTER_LOG_FILE='recorded_log_file_name',
    ->     MASTER_LOG_POS=recorded_log_position;
```

3. Execute START SLAVE on the slave.

If you do not have a backup of the master server, here is a quick procedure for creating one. All steps should be performed on the master host.

1. Issue this statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

2. With the lock still in place, execute this command (or a variation of it):

```
shell> tar zcf /tmp/backup.tar.gz /var/lib/mysql
```

3. Issue this statement and make sure to record the output, which you need later:

```
mysql> SHOW MASTER STATUS;
```

4.   Release the lock:

```
mysql> UNLOCK TABLES;
```

An alternative is to make an SQL dump of the master instead of a binary copy as in the preceding procedure. To do this, you can use `mysqldump --master-data` on your master and later load the SQL dump into your slave. However, this is slower than making a binary copy.

No matter which of the two methods you use, afterward follow the instructions for the case when you have a snapshot and have recorded the log name and offset. You can use the same snapshot to set up several slaves. Once you have the snapshot of the master, you can wait to set up a slave as long as the binary logs of the master are left intact. The two practical limitations on the length of time you can wait are the amount of disk space available to retain binary logs on the master and the length of time it takes the slave to catch up.

You can also use `LOAD DATA FROM MASTER`. This is a convenient statement that transfers a snapshot to the slave and adjusts the log name and offset all at once. In the future, `LOAD DATA FROM MASTER` will be the recommended way to set up a slave. Be warned, however, that it works only for `MyISAM` tables and it may hold a read lock for a long time. It is not yet implemented as efficiently as we would like. If you have large tables, the preferred method at this time is still to make a binary snapshot on the master server after executing `FLUSH TABLES WITH READ LOCK`.

Q: Does the slave need to be connected to the master all the time?

A: No, it does not. The slave can go down or stay disconnected for hours or even days, then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in sync with the master unless you take some special measures. In the future, we will have the option to block the master until at least one slave is in sync.

Q: How do I know how late a slave is compared to the master? In other words, how do I know the date of the last query replicated by the slave?

A: If the slave is 4.1.1 or newer, read the `Seconds_Behind_Master` column in `SHOW SLAVE STATUS`. For older versions, the following applies. This is possible only if `SHOW SLAVE STATUS` on the slave shows that the SQL thread is running (or for MySQL 3.23, that the slave thread is running), and that the thread has executed at least one event from the master. See Section 6.3, "Replication Implementation Details".

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp (this is why `TIMESTAMP` is well replicated). In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see `Time` values like 3600 for the slave SQL thread in `SHOW PROCESSLIST`. This would be because the slave is executing statements that are one hour old.

Q: How do I force the master to block updates until the slave catches up?

A: Use the following procedure:

1.   On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the log name and the offset from the output of the SHOW statement. These are the replication coordinates.

2. On the slave, issue the following statement, where the arguments to the MAS-TER_POS_WAIT() function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_offset);
```

The SELECT statement blocks until the slave reaches the specified log file and offset. At that point, the slave is in sync with the master and the statement returns.

3. On the master, issue the following statement to allow the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

Q: What issues should I be aware of when setting up two-way replication?

A: MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different than what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You must also realize that two-way replication actually does not improve performance very much (if at all), as far as updates are concerned. Both servers need to do the same number of updates each, as you would have one server do. The only difference is that there is a little less lock contention, because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

Q: How can I use replication to improve performance of my system?

A: You should set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the --skip-innodb, --skip-bdb, --low-priority-updates, and --delay-key-write=ALL options to get speed improvements on the slave end. In this case, the slave uses non-transactional MyISAM tables instead of InnoDB and BDB tables to get more speed.

Q: What should I do to prepare client code in my own applications to use performance-enhancing replication?

A: If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Just change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to it clean up. You should start by creating a wrapper library or module with the following functions:

*   safe_writer_connect()

*   safe_reader_connect()

*   safe_reader_statement()

- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

You should then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is a lot easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `re-place` utility that comes with standard MySQL distributions, or just write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

Q: When and how much can MySQL replication improve the performance of my system?

A: MySQL replication is most beneficial for a system with frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

In order to determine how many slaves you can get before the added benefits begin to level out, and how much you can improve performance of your site, you need to know your query patterns, and to determine empirically by benchmarking the relationship between the throughput for reads (reads per second, or `max_reads`) and for writes (`max_writes`) on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that `max_reads` is $1200 - 2 \times$ `max_writes`. In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Let us suppose that the master and each slave have the same capacity, and that we have one master and N slaves. Then we have for each server (master or slave):

```
reads = 1200 - 2 × writes
```

```
reads = 9 × writes / (N + 1)
```
(reads are split, but writes go to all servers)

```
9 × writes / (N + 1) + 2 × writes = 1200
```

```
writes = 1200 / (2 + 9/(N+1))
```

The last equation indicates that the maximum number of writes for N slaves, given a maximum possible read rate of 1,200 per minute and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If $N = 0$ (which means we have no replication), our system can handle about 1200/11 = 109 writes per second.

- If $N = 1$, we get up to 184 writes per second.

- If $N = 8$, we get up to 400 writes per second.

- If $N = 17$, we get up to 480 writes per second.

- Eventually, as N approaches infinity (and our budget negative infinity), we can get very close to

600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

Note that these computations assume infinite network bandwidth and neglect several other factors that could turn out to be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add *N* replication slaves. However, answering the following questions should help you decide if and by how much replication will improve the performance of your system:

* What is the read/write ratio on your system?

* How much more write load can one server handle if you reduce the reads?

* For how many slaves do you have bandwidth available on your network?

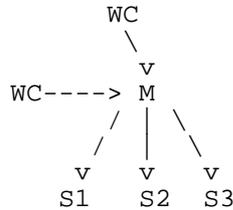
Q: How can I use replication to provide redundancy/high availability?

A: With the currently available features, you would have to set up a master and a slave (or several slaves), and to write a script that monitors the master to see if it is up. Then instruct your applications and the slaves to change master in case of failure. Some suggestions:

* To tell a slave to change its master, use the `CHANGE MASTER TO` statement.

* A good way to keep your applications informed as to the location of the master is by having a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to dynamically update your DNS.

* You should run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE`; `RESET MASTER`, and `CHANGE MASTER TO` on the other slaves. For example, assume that you have the following setup:

```
        WC
          \
            v
WC----> M
       / | \
      /  |  \
     v   v   v
    S1  S2  S3
```


M means the master, **S** the slaves, **WC** the clients issuing database writes and reads; clients that issue only database reads are not represented, because they need not switch. **S1**, **S2**, and **S3** are slaves running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty. If for some reason **M** becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick **S1**, all **WC** should be redirected to **S1**, and **S2** and **S3** should then replicate from **S1**.

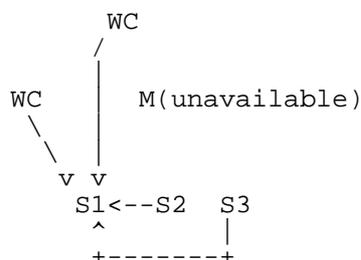
Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave **S1** being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves **S2** and **S3**, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='S1'` (where `'S1'` represents the real hostname of **S1**). To `CHANGE MASTER`, add all information about how to connect to **S1** from **S2** or **S3** (*user*, *password*, *port*). In `CHANGE MASTER`, there is no need to specify the name of **S1**'s binary log or binary log posi-

tion to read from: We know it is the first binary log and position 4, which are the defaults for `CHANGE MASTER`. Finally, use `START SLAVE` on **S2** and **S3**.

Then instruct all **WC** to direct their statements to **S1**. From that point on, all updates statements sent by **WC** to **S1** are written to the binary log of **S1**, which then contains every update statement sent to **S1** since **M** died.

The result is this configuration:

```
      WC
     /
    |
 WC │    M(unavailable)
   \  |
    \ |
     v v
     S1<--S2  S3
      ^       |
      +-------+
```


When **M** is up again, you must issue on it the same `CHANGE MASTER` as that issued on **S2** and **S3**, so that **M** becomes a slave of **S1** and picks up all the **WC** writes that it missed while it was down. To make **M** a master again (because it is the most powerful machine, for example), use the preceding procedure as if **S1** was unavailable and **M** was to be the new master. During this procedure, do not forget to run `RESET MASTER` on **M** before making **S1**, **S2**, and **S3** slaves of **M**. Otherwise, they may pick up old **WC** writes from before the point at which **M** became unavailable.

We are currently working on integrating an automatic master election system into MySQL, but until it is ready, you have to create your own monitoring tools.

6.10. Troubleshooting Replication

If you have followed the instructions, and your replication setup is not working, first check the following:

- **Check the error log for messages**. Many users have lost time by not doing this early enough after encountering problems.

- Is the master logging to the binary log? Check with `SHOW MASTER STATUS`. If it is, `Position` is non-zero. If not, verify that you are running the master with the `log-bin` and `server-id` options.

- Is the slave running? Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server.

- If the slave is running, did it establish a connection to the master? Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see how they display. See Section 6.3, "Replication Implementation Details". If the I/O thread state says `Connecting to master`, verify the privileges for the replication user on the master, master hostname, your DNS setup, whether the master is actually running, and whether it is reachable from the slave.

- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If it does, it is a bug or you have encountered one of the known replication limitations described in Section 6.7, "Replication Features and Known Problems". If it is a bug, see Section 6.11, "Reporting Replication Bugs" for instructions on how to report it.

- If a statement that succeeded on the master refuses to run on the slave, and it is not feasible to do a full database resynchronization (that is, to delete the slave's database and copy a new snapshot from the master), try the following:

    1. Determine whether the slave's table is different from the master's. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.

    2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.

    3. If you decide that you can skip the next statement from the master, issue the following statements:

       ```
       mysql> SET GLOBAL SQL_SLAVE_SKIP_COUNTER = n;
       mysql> START SLAVE;
       ```

       The value of `n` should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

    4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version, please report the problem. If you are running an older version of MySQL, try upgrading to the latest production release.

6.11. Reporting Replication Bugs

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database at http://bugs.mysql.com/. If you have a "phantom" problem (one that you cannot duplicate at will), then use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of sync, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them in sync. *This is not a replication problem. It is a problem with outside interference causing replication to fail.*

2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:

    - All binary logs from the master

    - All binary logs from the slave

    - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem

- The output of SHOW SLAVE STATUS from the master at the time you discovered the problem

- Error logs from the master and the slave

4. Use mysqlbinlog to examine the binary logs. The following should be helpful to find the problem query, for example:

```
shell> mysqlbinlog -j pos_from_slave_status \
         /path/to/log_from_slave_status | head
```

Once you have collected the evidence for the phantom problem, try hard to isolate it into a separate test case first. Then enter the problem into our bugs database at http://bugs.mysql.com/ with as much information as possible.

Chapter 7. MySQL Optimization

Optimization is a complex task because ultimately it requires understanding of the entire system to be optimized. Although it may be possible to perform some local optimizations with little knowledge of your system or application, the more optimal you want your system to become, the more you have to know about it.

This chapter tries to explain and give some examples of different ways to optimize MySQL. Remember, however, that there are always additional ways to make the system even faster, although they may require increasing effort to achieve.

7.1. Optimization Overview

The most important factor in making a system fast is its basic design. You also need to know what kinds of things your system is doing, and what your bottlenecks are.

The most common system bottlenecks are:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.

- Disk reading and writing. When the disk is at the correct position, we need to read the data. With modern disks, one disk delivers at least 10-20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.

- CPU cycles. When we have the data in main memory, we need to process it to get our result. Having small tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.

- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

7.1.1. MySQL Design Limitations and Tradeoffs

When using the `MyISAM` storage engine, MySQL uses extremely fast table locking that allows multiple readers or a single writer. The biggest problem with this storage engine occurs when you have a steady stream of mixed updates and slow selects on a single table. If this is a problem for certain tables, you can use another storage engine for them. See Chapter 14, *MySQL Storage Engines and Table Types*.

MySQL can work with both transactional and non-transactional tables. To be able to work smoothly with non-transactional tables (which can't roll back if something goes wrong), MySQL has the following rules (when not running in strict mode or if you use the `IGNORE` specifier to `INSERT` or `UPDATE`).

- All columns have default values.

- If you insert an "incorrect" value in a column, such as a too-large numeric value into a numeric column, MySQL sets the column to the "best possible value" instead of giving an error. For numerical values, this is 0, the smallest possible value or the largest possible value. For strings, this is either the empty string or as much of the string as can be stored in the column.

- All calculated expressions return a value that can be used instead of signaling an error condition. For example, 1/0 returns `NULL`. (This behavior can be changed by using the `ER-`

ROR_FOR_DIVISION_BY_ZERO SQL mode).

If you are using non-transactional tables, you should not use MySQL to check column content. In general, the safest (and often fastest) way is to let the application ensure that it passes only legal values to the database.

For more information about this, see Section 1.8.6, "How MySQL Deals with Constraints" and Section 13.2.4, "INSERT Syntax" or Section 5.3.2, "The Server SQL Mode".

7.1.2. Designing Applications for Portability

Because all SQL servers implement different parts of standard SQL, it takes work to write portable SQL applications. It is very easy to achieve portability for very simple selects and inserts, but becomes more difficult the more capabilities you require. If you want an application that is fast with many database systems, it becomes even harder!

To make a complex application portable, you need to determine which SQL servers it must work with, then determine what features those servers support.

All database systems have some weak points. That is, they have different design compromises that lead to different behavior.

You can use the MySQL crash-me program to find functions, types, and limits that you can use with a selection of database servers. crash-me does not check for every possible feature, but it is still reasonably comprehensive, performing about 450 tests.

An example of the type of information crash-me can provide is that you shouldn't have column names longer than 18 characters if you want to be able to use Informix or DB2.

The crash-me program and the MySQL benchmarks are all very database independent. By taking a look at how they are written, you can get a feeling for what you have to do to make your own applications database independent. The programs can be found in the sql-bench directory of MySQL source distributions. They are written in Perl and use the DBI database interface. Use of DBI in itself solves part of the portability problem because it provides database-independent access methods.

For crash-me results, visit http://dev.mysql.com/tech-resources/crash-me.php. See http://dev.mysql.com/tech-resources/benchmarks/ for the results from the benchmarks.

If you strive for database independence, you need to get a good feeling for each SQL server's bottlenecks. For example, MySQL is very fast in retrieving and updating records for MyISAM tables, but has a problem in mixing slow readers and writers on the same table. Oracle, on the other hand, has a big problem when you try to access rows that you have recently updated (until they are flushed to disk). Transactional databases in general are not very good at generating summary tables from log tables, because in this case row locking is almost useless.

To make your application *really* database independent, you need to define an easily extendable interface through which you manipulate your data. As C++ is available on most systems, it makes sense to use a C++ class-based interface to the databases.

If you use some feature that is specific to a given database system (such as the REPLACE statement, which is specific to MySQL), you should implement the same feature for other SQL servers by coding an alternative method. Although the alternative may be slower, it allows the other servers to perform the same tasks.

With MySQL, you can use the /*! */ syntax to add MySQL-specific keywords to a query. The code inside /**/ is treated as a comment (and ignored) by most other SQL servers.

If high performance is more important than exactness, as in some Web applications, it is possible to create an application layer that caches all results to give you even higher performance. By letting old results "expire" after a while, you can keep the cache reasonably fresh. This provides a method to handle high load spikes, in which case you can dynamically increase the cache and set the expiration

timeout higher until things get back to normal.

In this case, the table creation information should contain information of the initial size of the cache and how often the table should normally be refreshed.

An alternative to implementing an application cache is to use the MySQL query cache. By enabling the query cache, the server handles the details of determining whether a query result can be reused. This simplifies your application. See Section 5.12, "The MySQL Query Cache".

7.1.3. What We Have Used MySQL For

This section describes an early application for MySQL.

During MySQL initial development, the features of MySQL were made to fit our largest customer, which handled data warehousing for a couple of the largest retailers in Sweden.

From all stores, we got weekly summaries of all bonus card transactions, and were expected to provide useful information for the store owners to help them find how their advertising campaigns were affecting their own customers.

The volume of data was quite huge (about seven million summary transactions per month), and we had data for 4-10 years that we needed to present to the users. We got weekly requests from our customers, who wanted to get "instant" access to new reports from this data.

We solved this problem by storing all information per month in compressed "transaction" tables. We had a set of simple macros that generated summary tables grouped by different criteria (product group, customer id, store, and so on) from the tables in which the transactions were stored. The reports were Web pages that were dynamically generated by a small Perl script. This script parsed a Web page, executed the SQL statements in it, and inserted the results. We would have used PHP or mod_perl instead, but they were not available at the time.

For graphical data, we wrote a simple tool in C that could process SQL query results and produce GIF images based on those results. This tool also was dynamically executed from the Perl script that parses the Web pages.

In most cases, a new report could be created simply by copying an existing script and modifying the SQL query in it. In some cases, we needed to add more columns to an existing summary table or generate a new one. This also was quite simple because we kept all transaction-storage tables on disk. (This amounted to about 50GB of transaction tables and 200GB of other customer data.)

We also let our customers access the summary tables directly with ODBC so that the advanced users could experiment with the data themselves.

This system worked well and we had no problems handling the data with quite modest Sun Ultra SPARCstation hardware (2x200MHz). Eventually the system was migrated to Linux.

7.1.4. The MySQL Benchmark Suite

This section should contain a technical description of the MySQL benchmark suite (and `crash-me`), but that description has not yet been written. Currently, you can get a good idea of the benchmarks by looking at the code and results in the `sql-bench` directory in any MySQL source distribution.

This benchmark suite is meant to tell any user what operations a given SQL implementation performs well or poorly.

Note that this benchmark is single-threaded, so it measures the minimum time for the operations performed. We plan to add multi-threaded tests to the benchmark suite in the future.

To use the benchmark suite, the following requirements must be satisfied:

- The benchmark suite is provided with MySQL source distributions. You can either download a released distribution from http://dev.mysql.com/downloads/, or use the current development source tree (see Section 2.8.3, "Installing from the Development Source Tree").

- The benchmark scripts are written in Perl and use the Perl DBI module to access database servers, so DBI must be installed. You also need the server-specific DBD drivers for each of the servers you want to test. For example, to test MySQL, PostgreSQL, and DB2, you must have the `DBD::mysql`, `DBD::Pg`, and `DBD::DB2` modules installed. See Section 2.13, "Perl Installation Notes".

After you obtain a MySQL source distribution, you can find the benchmark suite located in its `sql-bench` directory. To run the benchmark tests, build MySQL, then change location into the `sql-bench` directory and execute the `run-all-tests` script:

```
shell> cd sql-bench
shell> perl run-all-tests --server=server_name
```

`server_name` is one of the supported servers. To get a list of all options and supported servers, invoke this command:

```
shell> perl run-all-tests --help
```

The `crash-me` script also is located in the `sql-bench` directory. `crash-me` tries to determine what features a database supports and what its capabilities and limitations are by actually running queries. For example, it determines:

- What column types are supported

- How many indexes are supported

- What functions are supported

- How big a query can be

- How big a `VARCHAR` column can be

You can find the results from `crash-me` for many different database servers at http://dev.mysql.com/tech-resources/crash-me.php. For more information about benchmark results, visit http://dev.mysql.com/tech-resources/benchmarks/.

7.1.5. Using Your Own Benchmarks

You should definitely benchmark your application and database to find out where the bottlenecks are. By fixing a bottleneck (or by replacing it with a "dummy module"), you can then easily identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck, and decide how to solve it if someday you really need the extra performance.

For an example of portable benchmark programs, look at the MySQL benchmark suite. See Section 7.1.4, "The MySQL Benchmark Suite". You can take any program from this suite and modify it for your needs. By doing this, you can try different solutions to your problem and test which really is fastest for you.

Another free benchmark suite is the Open Source Database Benchmark, available at http://osdb.sourceforge.net/.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have en-

countered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are *not good* at high load) or problems with the operating system or libraries. Most of the time, these problems would be a *lot* easier to fix if the systems were not in production.

To avoid problems like this, you should put some effort into benchmarking your whole application under the worst possible load! You can use Super Smack for this. It is available at http://jeremy.zawodny.com/mysql/super-smack/. As the name suggests, it can bring a system to its knees if you ask it, so make sure to use it only on your development systems.

7.2. Optimizing `SELECT` Statements and Other Queries

First, one factor affects all statements: The more complex your permission setup is, the more overhead you have.

Using simpler permissions when you issue `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you don't grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high query volume, it may be worth the time to use a simplified grant structure to reduce permission-checking overhead.

If your problem is with some specific MySQL expression or function, you can use the `BENCH-MARK()` function from the `mysql` client program to perform a timing test. Its syntax is `BENCH-MARK(loop_count,expression)`. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+-------------------------+
| BENCHMARK(1000000,1+1) |
+-------------------------+
|                       0 |
+-------------------------+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

All MySQL functions should be very optimized, but there may be some exceptions. `BENCH-MARK()` is a great tool to find out if this is a problem with your query.

7.2.1. `EXPLAIN` Syntax (Get Information About a `SELECT`)

```
EXPLAIN tbl_name
```

Or:

```
EXPLAIN SELECT select_options
```

The `EXPLAIN` statement can be used either as a synonym for `DESCRIBE` or as a way to obtain information about how MySQL executes a `SELECT` statement:

- The `EXPLAIN` *tbl_name* syntax is synonymous with `DESCRIBE` *tbl_name* or `SHOW COLUMNS FROM` *tbl_name*.

- When you precede a `SELECT` statement with the keyword `EXPLAIN`, MySQL explains how it

would process the SELECT, providing information about how tables are joined and in which order.

This section provides information about the second use of EXPLAIN.

With the help of EXPLAIN, you can see when you must add indexes to tables to get a faster SELECT that uses indexes to find records.

If you have a problem with incorrect index usage, you should run ANALYZE TABLE to update table statistics such as cardinality of keys, which can affect the choices the optimizer makes. See Section 13.5.2.1, "ANALYZE TABLE Syntax".

You can also see whether the optimizer joins the tables in an optimal order. To force the optimizer to use a join order corresponding to the order in which the tables are named in the SELECT statement, begin the statement with SELECT STRAIGHT_JOIN rather than just SELECT.

EXPLAIN returns a row of information for each table used in the SELECT statement. The tables are listed in the output in the order that MySQL would read them while processing the query. MySQL resolves all joins using a single-sweep multi-join method. This means that MySQL reads a row from the first table, then finds a matching row in the second table, then in the third table, and so on. When all tables are processed, it outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

In MySQL version 4.1, the EXPLAIN output format was changed to work better with constructs such as UNION statements, subqueries, and derived tables. Most notable is the addition of two new columns: id and select_type. You do not see these columns when using servers older than MySQL 4.1.

Each output row from EXPLAIN provides information about one table, and each row consists of the following columns:

- id

  The SELECT identifier. This is the sequential number of the SELECT within the query.

- select_type

  The type of SELECT, which can be any of the following:

  - SIMPLE

    Simple SELECT (not using UNION or subqueries)

  - PRIMARY

    Outermost SELECT

  - UNION

    Second or later SELECT statement in a UNION

  - DEPENDENT UNION

    Second or later SELECT statement in a UNION, dependent on outer query

  - UNION RESULT

    Result of a UNION.

  - SUBQUERY

First `SELECT` in subquery

- `DEPENDENT SUBQUERY`

  First `SELECT` in subquery, dependent on outer query

- `DERIVED`

  Derived table `SELECT` (subquery in `FROM` clause)

- `table`

  The table to which the row of output refers.

- `type`

  The join type. The different join types are listed here, ordered from the best type to the worst:

  - `system`

    The table has only one row (= system table). This is a special case of the `const` join type.

  - `const`

    The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` tables are very fast because they are read only once!

    `const` is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index with constant values. In the following queries, `tbl_name` can be used as a `const` table:

    ```
    SELECT * FROM tbl_name WHERE primary_key=1;

    SELECT * FROM tbl_name
    WHERE primary_key_part1=1 AND primary_key_part2=2;
    ```

  - `eq_ref`

    One row is read from this table for each combination of rows from the previous tables. Other than the `const` types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE` index.

    `eq_ref` can be used for indexed columns that are compared using the = operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table.

    In the following examples, MySQL can use an `eq_ref` join to process `ref_table`:

    ```
    SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column=other_table.column;

    SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column_part1=other_table.column
    AND ref_table.key_column_part2=1;
    ```

  - `ref`

    All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` is used if the join uses only a leftmost prefix of the key or if

the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

`ref` can be used for indexed columns that are compared using the `=` or `<=>` operator.

In the following examples, MySQL can use a `ref` join to process *ref_table*:

```
SELECT * FROM ref_table WHERE key_column=expr;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- `ref_or_null`

  This join type is like `ref`, but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is new for MySQL 4.1.1 and is mostly used when resolving subqueries.

  In the following examples, MySQL can use a `ref_or_null` join to process *ref_table*:

  ```
  SELECT * FROM ref_table
  WHERE key_column=expr OR key_column IS NULL;
  ```

  See Section 7.2.7, "How MySQL Optimizes `IS NULL`".

- `index_merge`

  This join type indicates that the Index Merge optimization is used. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see Section 7.2.6, "Index Merge Optimization".

- `unique_subquery`

  This type replaces `ref` for some `IN` subqueries of the following form:

  ```
  value IN (SELECT primary_key FROM single_table WHERE some_expr)
  ```

  `unique_subquery` is just an index lookup function that replaces the subquery completely for better efficiency.

- `index_subquery`

  This join type is similar to `unique_subquery`. It replaces `IN` subqueries, but it works for non-unique indexes in subqueries of the following form:

  ```
  value IN (SELECT key_column FROM single_table WHERE some_expr)
  ```

- `range`

  Only rows that are in a given range are retrieved, using an index to select the rows. The `key` column indicates which index is used. The `key_len` contains the longest key part that was used. The `ref` column is `NULL` for this type.

  `range` can be used for when a key column is compared to a constant using any of the `=`, `<>`, `>`, `>=`, `<`, `<=`, `IS NULL`, `<=>`, `BETWEEN`, or `IN` operators:

```
SELECT * FROM tbl_name
WHERE key_column = 10;

SELECT * FROM tbl_name
WHERE key_column BETWEEN 10 and 20;

SELECT * FROM tbl_name
WHERE key_column IN (10,20,30);

SELECT * FROM tbl_name
WHERE key_part1= 10 AND key_part2 IN (10,20,30);
```

- `index`

  This join type is the same as `ALL`, except that only the index tree is scanned. This usually is faster than `ALL`, because the index file usually is smaller than the data file.

  MySQL can use this join type when the query uses only columns that are part of a single index.

- `ALL`

  A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const`, and usually *very* bad in all other cases. Normally, you can avoid `ALL` by adding indexes that allow row retrieval from the table based on constant values or column values from earlier tables.

- `possible_keys`

  The `possible_keys` column indicates which indexes MySQL could use to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

  If this column is `NULL`, there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to see whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with `EXPLAIN` again. See Section 13.1.2, "`ALTER TABLE` Syntax".

  To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- `key`

  The `key` column indicates the key (index) that MySQL actually decided to use. The key is `NULL` if no index was chosen. To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See Section 13.2.7, "`SELECT` Syntax".

  For `MyISAM` and `BDB` tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For `MyISAM` tables, `myisamchk --analyze` does the same. See Section 13.5.2.1, "`ANALYZE TABLE` Syntax" and Section 5.8.4, "Table Maintenance and Crash Recovery".

- `key_len`

  The `key_len` column indicates the length of the key that MySQL decided to use. The length is `NULL` if the `key` column says `NULL`. Note that the value of `key_len` allows you to determine how many parts of a multiple-part key MySQL actually uses.

- `ref`

  The `ref` column shows which columns or constants are used with the `key` to select rows from the table.

- rows

  The rows column indicates the number of rows MySQL believes it must examine to execute the query.

- Extra

  This column contains additional information about how MySQL resolves the query. Here is an explanation of the different text strings that can appear in this column:

  - Distinct

    MySQL stops searching for more rows for the current row combination after it has found the first matching row.

  - Not exists

    MySQL was able to do a LEFT JOIN optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the LEFT JOIN criteria.

    Here is an example of the type of query that can be optimized this way:

    ```
    SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
    WHERE t2.id IS NULL;
    ```

    Assume that t2.id is defined as NOT NULL. In this case, MySQL scans t1 and looks up the rows in t2 using the values of t1.id. If MySQL finds a matching row in t2, it knows that t2.id can never be NULL, and does not scan through the rest of the rows in t2 that have the same id value. In other words, for each row in t1, MySQL needs to do only a single lookup in t2, regardless of how many rows actually match in t2.

  - range checked for each record (index map: #)

    MySQL found no good index to use, but found that some of indexes might be used once column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a range or index_merge access method to retrieve rows. The applicability criteria are as described in Section 7.2.5, "Range Optimization" and Section 7.2.6, "Index Merge Optimization", with the exception that all column values for the preceding table are known and considered to be constants.

    This is not very fast, but is faster than performing a join with no index at all.

  - Using filesort

    MySQL needs to do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the WHERE clause. The keys then are sorted and the rows are retrieved in sorted order. See Section 7.2.12, "How MySQL Optimizes ORDER BY".

  - Using index

    The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

  - Using temporary

    To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains GROUP BY and ORDER BY clauses that list columns differently.

- Using where

  A WHERE clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the Extra value is not Using where and the table join type is ALL or index.

  If you want to make your queries as fast as possible, you should look out for Extra values of Using filesort and Using temporary.

- Using sort_union(...), Using union(...), Using intersect(...)

  These indicate how index scans are merged for the index_merge join type. See Section 7.2.6, "Index Merge Optimization" for more information.

- Using index for group-by

  Similar to the Using index way of accessing a table, Using index for group-by indicates that MySQL found an index that can be used to retrieve all columns of a GROUP BY or DISTINCT query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see Section 7.2.13, "How MySQL Optimizes GROUP BY".

You can get a good indication of how good a join is by taking the product of the values in the rows column of the EXPLAIN output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the max_join_size system variable, this product also is used to determine which multiple-table SELECT statements to execute. See Section 7.5.2, "Tuning Server Parameters".

The following example shows how a multiple-table join can be optimized progressively based on the information provided by EXPLAIN.

Suppose that you have the SELECT statement shown here and you plan to examine it using EXPLAIN:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
            tt.ProjectReference, tt.EstimatedShipDate,
            tt.ActualShipDate, tt.ClientID,
            tt.ServiceCodes, tt.RepetitiveID,
            tt.CurrentProcess, tt.CurrentDPPerson,
            tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
            et_1.COUNTRY, do.CUSTNAME
        FROM tt, et, et AS et_1, do
        WHERE tt.SubmitTime IS NULL
            AND tt.ActualPC = et.EMPLOYID
            AND tt.AssignedPC = et_1.EMPLOYID
            AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows:

Table	Column	Column Type
tt	ActualPC	CHAR(10)
tt	AssignedPC	CHAR(10)
tt	ClientID	CHAR(10)
et	EMPLOYID	CHAR(15)
do	CUSTNMBR	CHAR(15)

- The tables have the following indexes:

Table	Index
tt	ActualPC
tt	AssignedPC
tt	ClientID
et	EMPLOYID (primary key)
do	CUSTNMBR (primary key)

- The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the EXPLAIN statement produces the following information:

```
table type possible_keys key  key_len ref   rows  Extra
et    ALL  PRIMARY       NULL NULL    NULL 74
do    ALL  PRIMARY       NULL NULL    NULL 2135
et_1  ALL  PRIMARY       NULL NULL    NULL 74
tt    ALL  AssignedPC,   NULL NULL    NULL 3872
           ClientID,
           ActualPC
      range checked for each record (key map: 35)
```

Because `type` is ALL for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is 74 * 2135 * 74 * 3872 = 45,268,558,720 rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared the same. (For ISAM tables, indexes may not be used at all unless the columns are declared the same.) In this context, VARCHAR and CHAR are the same unless they are declared as different lengths. Because `tt.ActualPC` is declared as CHAR(10) and `et.EMPLOYID` is declared as CHAR(15), there is a length mismatch.

To fix this disparity between column lengths, use ALTER TABLE to lengthen `ActualPC` from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

`tt.ActualPC` and `et.EMPLOYID` are both VARCHAR(15). Executing the EXPLAIN statement again produces this result:

```
table type    possible_keys key     key_len ref        rows  Extra
tt    ALL     AssignedPC,   NULL    NULL    NULL       3872  Using
              ClientID,                                      where
              ActualPC
do    ALL     PRIMARY       NULL    NULL    NULL       2135
      range checked for each record (key map: 1)
et_1  ALL     PRIMARY       NULL    NULL    NULL       74
      range checked for each record (key map: 1)
et    eq_ref  PRIMARY       PRIMARY 15      tt.ActualPC 1
```

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version is executed in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
    ->                 MODIFY ClientID   VARCHAR(15);
```

EXPLAIN produces the output shown here:

table	type	possible_keys	key	key_len	ref	rows	Extra
et	ALL	PRIMARY	NULL	NULL	NULL	74	
tt	ref	AssignedPC, ClientID, ActualPC	ActualPC	15	et.EMPLOYID	52	Using where
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

This is almost as good as it can get.

The remaining problem is that, by default, MySQL assumes that values in the tt.ActualPC column are evenly distributed, and that is not the case for the tt table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

The join is perfect, and EXPLAIN produces this result:

table	type	possible_keys	key	key_len	ref	rows	Extra
tt	ALL	AssignedPC ClientID, ActualPC	NULL	NULL	NULL	3872	Using where
et	eq_ref	PRIMARY	PRIMARY	15	tt.ActualPC	1	
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

Note that the rows column in the output from EXPLAIN is an educated guess from the MySQL join optimizer. You should check whether the numbers are even close to the truth. If not, you may get better performance by using STRAIGHT_JOIN in your SELECT statement and trying to list the tables in a different order in the FROM clause.

7.2.2. Estimating Query Performance

In most cases, you can estimate the performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row: $\log(row\_count) / \log(index\_block\_length / 3 * 2 / (index\_length + data\_pointer\_length)) + 1$.

In MySQL, an index block is usually 1024 bytes and the data pointer is usually 4 bytes. For a 500,000-row table with an index length of 3 bytes (medium integer), the formula indicates $\log(500,000)/\log(1024/3*2/(3+4)) + 1 = 4$ seeks.

This index would require storage of about 500,000 * 7 * 3/2 = 5.2MB (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and you probably need only one or two calls to read data to find the row.

For writes, however, you need four seek requests (as above) to find where to place the new index and normally two seeks to update the index and write the row.

Note that the preceding discussion doesn't mean that your application performance slowly degenerates by log N. As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are only bound by disk-seeks (which increase by log *N*). To avoid this, increase the key cache size as the data grows. For MyISAM tables, the key cache size is controlled by the key_buffer_size system variable. See Section 7.5.2, "Tuning Server Para-

meters".

7.2.3. Speed of `SELECT` Queries

In general, when you want to make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an index. All references between different tables should usually be done with indexes. You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See Section 7.4.5, "How MySQL Uses Indexes" and Section 7.2.1, "EXPLAIN Syntax (Get Information About a `SELECT`)".

Some general tips for speeding up queries on `MyISAM` tables:

- To help MySQL optimize queries better, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a non-constant expression. You can check the result from the table analysis by using `SHOW INDEX FROM `*`tbl_name`*` and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.

- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (if you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all records in order according to the index. Note that the first time you sort a large table this way, it may take a long time.

7.2.4. How MySQL Optimizes `WHERE` Clauses

This section discusses optimizations that can be made for processing `WHERE` clauses. The examples use `SELECT` statements, but the same optimizations apply for `WHERE` clauses in `DELETE` and `UPDATE` statements.

Note that work on the MySQL optimizer is ongoing, so this section is incomplete. MySQL does many optimizations, not all of which are documented here.

Some of the optimizations performed by MySQL are listed here:

- Removal of unnecessary parentheses:

```
   ((a AND b) AND c OR (((a AND b) AND (c AND d)))) 
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
   (a<b AND b=c) AND a=5 
-> b>5 AND b=c AND a=5
```

- Constant condition removal (needed because of constant folding):

```
   (B>=5 AND B=5) OR (B=6 AND 5=5) OR (B=7 AND 5=6) 
-> B=5 OR B=6
```

- Constant expressions used by indexes are evaluated only once.

- `COUNT(*)` on a single table without a `WHERE` is retrieved directly from the table information for `MyISAM` and `HEAP` tables. This is also done for any `NOT NULL` expression when used with only one table.

- Early detection of invalid constant expressions. MySQL quickly detects that some `SELECT`

statements are impossible and returns no rows.

- `HAVING` is merged with `WHERE` if you don't use `GROUP BY` or group functions (`COUNT()`, `MIN()`, and so on).

- For each table in a join, a simpler `WHERE` is constructed to get a fast `WHERE` evaluation for the table and also to skip records as soon as possible.

-

  All constant tables are read first before any other tables in the query. A constant table is any of the following:

  - An empty table or a table with one row.

  - A table that is used with a `WHERE` clause on a `PRIMARY KEY` or a `UNIQUE` index, where all index parts are compared to constant expressions and are defined as `NOT NULL`.

  All of the following tables are used as constant tables:

  ```
  SELECT * FROM t WHERE primary_key=1;
  SELECT * FROM t1,t2
      WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
  ```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in `ORDER BY` and `GROUP BY` clauses come from the same table, that table is preferred first when joining.

- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.

- If you use `SQL_SMALL_RESULT`, MySQL uses an in-memory temporary table.

- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table. The optimizer is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size, so a fixed percentage no longer determines the choice between using an index or a scan.

- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.

- Before each record is output, those that do not match the `HAVING` clause are skipped.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;

SELECT MAX(key_part2) FROM tbl_name
    WHERE key_part1=constant;

SELECT ... FROM tbl_name
    ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
    ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

The following queries are resolved using only the index tree, assuming that the indexed columns are numeric:

```
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
    WHERE key_part1=val1 AND key_part2=val2;

SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```
SELECT ... FROM tbl_name
    ORDER BY key_part1,key_part2,... ;

SELECT ... FROM tbl_name
    ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

7.2.5. Range Optimization

The `range` access method uses a single index to retrieve a subset of table records that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. A detailed description of how intervals are extracted from the WHERE clause is given in the following sections.

7.2.5.1. Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the WHERE clause, so we'll talk about "range conditions" instead of intervals.

The definition of a range condition for a single-part index is as follows:

- For both BTREE and HASH indexes, comparison of a key part with a constant value is a range condition when using the =, <=>, IN, IS NULL, or IS NOT NULL operators.

- For BTREE indexes, comparison of a key part with a constant value is a range condition when using the >, <, >=, <=, BETWEEN, !=, or <> operators, or LIKE 'pattern' (where 'pattern' doesn't start with a wildcard).

- For all types of indexes, multiple range conditions combined with OR or AND form a range condition.

"Constant value" in the preceding descriptions means one of the following:

- A constant from the query string

- A column of a const or system table from the same join

- The result of an uncorrelated subquery

- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the WHERE clause:

```
SELECT * FROM t1 WHERE key_col > 1 AND key_col < 10;

SELECT * FROM t1 WHERE key_col = 1 OR key_col IN (15,18,20);

SELECT * FROM t1 WHERE key_col LIKE 'ab%' OR key_col BETWEEN
'bar' AND 'foo';
```

Note that some non-constant values may be converted to constants during the constant propagation phase.

MySQL tries to extract range conditions from the WHERE clause for each of the possible indexes. During the extraction process, conditions that can't be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

For example, consider the following statement, where key1 is an indexed column and nonkey is not indexed:

```
SELECT * FROM t1 WHERE
   (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
   (key1 < 'bar' AND nonkey = 4) OR
   (key1 < 'uux' AND key1 > 'z');
```

The extraction process for key key1 is as follows:

1. Start with original WHERE clause:

    ```
    (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
    (key1 < 'bar' AND nonkey = 4) OR
    (key1 < 'uux' AND key1 > 'z')
    ```

2. Remove nonkey = 4 and key1 LIKE '%b' because they cannot be used for a range scan. The right way to remove them is to replace them with TRUE, so that we don't miss any matching records when doing the range scan. Having replaced them with TRUE, we get:

    ```
    (key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
    (key1 < 'bar' AND TRUE) OR
    (key1 < 'uux' AND key1 > 'z')
    ```

3. Collapse conditions that are always true or false:

    *   (key1 LIKE 'abcde%' OR TRUE) is always true

    *   (key1 < 'uux' AND key1 > 'z') is always false

    Replacing these conditions with constants, we get:

    ```
    (key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
    ```

    Removing unnecessary TRUE and FALSE constants, we obtain

    ```
    (key1 < 'abc') OR (key1 < 'bar')
    ```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

    ```
    (key1 < 'bar')
    ```

In general (and as demonstrated in the example), the condition used for a range scan is less restrictive than the WHERE clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full WHERE clause.

The range condition extraction algorithm can handle nested AND/OR constructs of arbitrary depth, and its output doesn't depend on the order in which conditions appear in WHERE clause.

7.2.5.2. Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index records to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as key1(*key_part1*, *key_part2*, *key_part3*), and the following set of key tuples listed in key order:

```
key_part1   key_part2   key_part3
  NULL         1          'abc'
  NULL         1          'xyz'
  NULL         2          'foo'
   1           1          'abc'
   1           1          'xyz'
   1           2          'abc'
   2           1          'aaa'
```

The condition *key_part1* = 1 defines this interval:

```
(1, -inf, -inf) <= (key_part1, key_part2, key_part3) < (1, +inf, +inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition *key_part3* = 'abc' does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For HASH indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

```
    key_part1 cmp const1
AND key_part2 cmp const2
AND ...
AND key_partN cmp constN;
```

Here, *const1*, *const2*, ... are constants, *cmp* is one of the =, <=>, or IS NULL comparison operators, and the conditions cover all index parts. (That is, there are *N* conditions, one for each part of an *N*-part index.)

See Section 7.2.5.1, "Range Access Method for Single-Part Indexes" for the definition of what is considered to be a constant.

For example, the following is a range condition for a three-part HASH index:

```
key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
```

- For a BTREE index, an interval might be usable for conditions combined with AND, where each condition compares a key part with a constant value using =, <=>, IS NULL, >, <, >=, <=, !=, <>, BETWEEN, or LIKE '*pattern*' (where '*pattern*' doesn't start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all records that match the condition (or two intervals if <> or != is used). For example, for this condition:

```
key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
```

The single interval is:

```
('foo', 10, 10)
    < (key_part1, key_part2, key_part3)
        < ('foo', +inf, +inf)
```

It is possible that the created interval contains more records than the initial condition. For example, the preceding interval includes the value (`'foo', 11, 0`), which does not satisfy the original condition.

• If conditions that cover sets of records contained within intervals are combined with OR, they form a condition that covers a set of records contained within the union of their intervals. If the conditions are combined with AND, they form a condition that covers a set of records contained within the intersection of their intervals. For example, for this condition on a two-part index:

```
(key_part1 = 1 AND key_part2 < 2)
OR (key_part1 > 5)
```

The intervals is:

```
(1, -inf) < (key_part1, key_part2) < (1, 2)
(5, -inf) < (key_part1, key_part2)
```

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The `key_len` column in the EXPLAIN output indicates the maximum length of the key prefix used.

In some cases, `key_len` may indicate that a key part was used, but that might be not what you would expect. Suppose that *key_part1* and *key_part2* can be NULL. Then the `key_len` column displays two key part lengths for the following condition:

```
key_part1 >= 1 AND key_part2 < 2
```

But in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

Section 7.2.5.1, "Range Access Method for Single-Part Indexes" describes how optimizations are performed to combine or eliminate intervals for range conditions on single-part index. Analogous steps are performed for range conditions on multiple-part keys.

7.2.6. Index Merge Optimization

The Index Merge (`index_merge`) method is used to retrieve rows with several ref, `ref_or_null`, or range scans and merge the results into one. This method is employed when the table condition is a disjunction of conditions for which ref, `ref_or_null`, or range could be used with different keys.

This "join" type optimization is new in MySQL 5.0.0, and represents a significant change in behavior with regard to indexes, because the *old* rule was that the server is only ever able to use at most one index for each referenced table.

In EXPLAIN output, this method appears as `index_merge` in the type column. In this case, the key column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

Examples:

```
SELECT * FROM tbl_name WHERE key_part1 = 10 OR key_part2 = 20;

SELECT * FROM tbl_name
    WHERE (key_part1 = 10 OR key_part2 = 20) AND non_key_part=30;

SELECT * FROM t1, t2
    WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
    AND t2.key1=t1.some_col;

SELECT * FROM t1, t2
    WHERE t1.key1=1
    AND (t2.key1=t1.some_col OR t2.key2=t1.some_col2);
```

The Index Merge method has several access algorithms (seen in the `Extra` field of EXPLAIN output):

- intersection

- union

- sort-union

The following sections describe these methods in greater detail.

Note: The Index Merge optimization algorithm has the following known deficiencies:

- If a range scan is possible on some key, an Index Merge is not considered. For example, consider this query:

  ```
  SELECT * FROM t1 WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
  ```

  For this query, two plans are possible:

  1. An Index Merge scan using the `(goodkey1 < 10 OR goodkey2 < 20)` condition.

  2. A range scan using the `badkey < 30` condition.

  However, the optimizer only considers the second plan. If that is not what you want, you can make the optimizer consider `index_merge` by using IGNORE INDEX or FORCE INDEX. The following queries are executed using Index Merge:

  ```
  SELECT * FROM t1 FORCE INDEX(goodkey1,goodkey2)
  WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;

  SELECT * FROM t1 IGNORE INDEX(badkey)
  WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
  ```

- If your query has a complex WHERE clause with deep AND/OR nesting and MySQL doesn't choose the optimal plan, try distributing terms using the following identity laws:

  ```
  (x AND y) OR z = (x OR z) AND (y OR z)
  (x OR y) AND z = (x AND z) OR (y AND z)
  ```

The choice between different possible variants of the `index_merge` access method and other access methods is based on cost estimates of various available options.

7.2.6.1. Index Merge Intersection Access Algorithm

This access algorithm can be employed when a `WHERE` clause was converted to several range conditions on different keys combined with `AND`, and each condition is one of the following:

- In this form, where the index has exactly *N* parts (that is, all index parts are covered):

  `key_part1=const1 AND key_part2=const2 ... AND key_partN=constN`

- Any range condition over a primary key of an `InnoDB` or `BDB` table.

Here are some examples:

`SELECT * FROM innodb_table WHERE primary_key < 10 AND key_col1=20;`

`SELECT * FROM tbl_name`
`WHERE (key1_part1=1 AND key1_part2=2) AND key2=2;`

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table records are not retrieved and (EXPLAIN output contains `Using index` in `Extra` field in this case). Here is an example of such query:

`SELECT COUNT(*) FROM t1 WHERE key1=1 AND key2=1;`

If the used indexes don't cover all columns used in the query, full records are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over a primary key of an `InnoDB` or `BDB` table, it is not used for record retrieval, but is used to filter out records retrieved using other conditions.

7.2.6.2. Index Merge Union Access Algorithm

The applicability criteria for this algorithm are similar to those of the Index Merge method intersection algorithm. The algorithm can be employed when the table `WHERE` clause was converted to several range conditions on different keys combined with `OR`, and each condition is one of the following:

- In this form, where the index has exactly *N* parts (that is, all index parts are covered):

  `key_part1=const1 AND key_part2=const2 ... AND key_partN=constN`

- Any range condition over a primary key of an `InnoDB` or `BDB` table.

- A condition for which the Index Merge method intersection algorithm is applicable.

Here are some examples:

`SELECT * FROM t1 WHERE key1=1 OR key2=2 OR key3=3;`

`SELECT * FROM innodb_table WHERE (key1=1 AND key2=2) OR`
`  (key3='foo' AND key4='bar') AND key5=5;`

7.2.6.3. Index Merge Sort-Union Access Algorithm

This access algorithm is employed when the `WHERE` clause was converted to several range condi-

tions combined by `OR`, but for which the Index Merge method union algorithm is not applicable.

Here are some examples:

```
SELECT * FROM tbl_name WHERE key_col1 < 10 OR key_col2 < 20;

SELECT * FROM tbl_name
    WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col=30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all records and sort them before returning any records.

7.2.7. How MySQL Optimizes `IS NULL`

MySQL can do the same optimization on `col_name IS NULL` that it can do with `col_name = constant_value`. For example, MySQL can use indexes and ranges to search for `NULL` with `IS NULL`.

```
SELECT * FROM tbl_name WHERE key_col IS NULL;

SELECT * FROM tbl_name WHERE key_col <=> NULL;

SELECT * FROM tbl_name
    WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a `WHERE` clause includes a `col_name IS NULL` condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway; for example, if it comes from a table on the right side of a `LEFT JOIN`.

MySQL 4.1.1 and up can additionally optimize the combination `col_name = expr AND col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` when this optimization is used.

This optimization can handle one `IS NULL` for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;

SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;

SELECT * FROM t1, t2
    WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;

SELECT * FROM t1, t2
    WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);

SELECT * FROM t1, t2
    WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
    OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

Note that the optimization can handle only one `IS NULL` level. In the following query, MySQL uses key lookups only on the expression (`t1.a=t2.a AND t2.a IS NULL`) and is not able to use the key part on `b`:

```
SELECT * FROM t1, t2
    WHERE (t1.a=t2.a AND t2.a IS NULL)
    OR (t1.b=t2.b AND t2.b IS NULL);
```

7.2.8. How MySQL Optimizes `DISTINCT`

`DISTINCT` combined with `ORDER BY` needs a temporary table in many cases.

Note that because `DISTINCT` may use `GROUP BY`, you should be aware of how MySQL works with columns in `ORDER BY` or `HAVING` clauses that are not part of the selected columns. See Section 12.10.3, "`GROUP BY` with Hidden Fields".

In most cases, a `DISTINCT` clause can be considered as a special case of `GROUP BY`. For example, the following two queries are equivalent:

```
SELECT DISTINCT c1, c2, c3 FROM t1 WHERE c1 > const;
```

```
SELECT c1, c2, c3 FROM t1 WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to `GROUP BY` queries can be also applied to queries with a `DISTINCT` clause. Thus, for more details on the optimization possibilities for `DISTINCT` queries, see Section 7.2.13, "How MySQL Optimizes `GROUP BY`".

When combining `LIMIT` *row_count* with `DISTINCT`, MySQL stops as soon as it finds *row_count* unique rows.

If you don't use columns from all tables named in a query, MySQL stops scanning the not-used tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with `EXPLAIN`), MySQL stops reading from `t2` (for any particular row in `t1`) when the first row in `t2` is found:

```
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

7.2.9. How MySQL Optimizes `LEFT JOIN` and `RIGHT JOIN`

A `LEFT JOIN B join_condition` is implemented in MySQL as follows:

- Table `B` is set to depend on table `A` and all tables on which `A` depends.

- Table `A` is set to depend on all tables (except `B`) that are used in the `LEFT JOIN` condition.

- The `LEFT JOIN` condition is used to decide how to retrieve rows from table B. (In other words, any condition in the `WHERE` clause is not used.)

- All standard join optimizations are done, with the exception that a table is always read after all tables on which it depends. If there is a circular dependence, MySQL issues an error.

- All standard `WHERE` optimizations are done.

- If there is a row in `A` that matches the `WHERE` clause, but there is no row in `B` that matches the `ON` condition, an extra `B` row is generated with all columns set to `NULL`.

- If you use `LEFT JOIN` to find rows that don't exist in some table and you have the following test: *col_name* `IS NULL` in the `WHERE` part, where *col_name* is a column that is declared as `NOT NULL`, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the `LEFT JOIN` condition.

`RIGHT JOIN` is implemented analogously to `LEFT JOIN`, with the roles of the tables reversed.

The join optimizer calculates the order in which tables should be joined. The table read order forced by LEFT JOIN and STRAIGHT_JOIN helps the join optimizer do its work much more quickly, because there are fewer table permutations to check. Note that this means that if you do a query of the following type, MySQL does a full scan on b because the LEFT JOIN forces it to be read before d:

```
SELECT *
    FROM a,b LEFT JOIN c ON (c.key=a.key) LEFT JOIN d ON (d.key=a.key)
    WHERE b.key=d.key;
```

The fix in this case is to rewrite the query as follows:

```
SELECT *
    FROM b,a LEFT JOIN c ON (c.key=a.key) LEFT JOIN d ON (d.key=a.key)
    WHERE b.key=d.key;
```

Starting from 4.0.14, MySQL does the following LEFT JOIN optimization: If the WHERE condition is always false for the generated NULL row, the LEFT JOIN is changed to a normal join.

For example, the WHERE clause would be false in the following query if t2.column1 would be NULL:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it's safe to convert the query to a normal join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

This can be made faster because MySQL can use table t2 before table t1 if this would result in a better query plan. To force a specific table order, use STRAIGHT_JOIN.

7.2.10. How MySQL Optimizes Nested Joins

As of MySQL 5.0.1, the syntax for expressing joins allows nested joins. The following discussion refers to the join syntax described in Section 13.2.7.1, "JOIN Syntax".

The syntax of *table_factor* is extended in comparison with the SQL Standard. The latter accepts only *table_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of *table_reference* items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
                ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to :

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
                ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, CROSS JOIN is a syntactic equivalent to INNER JOIN (they can replace each other. In standard SQL, they are not equivalent. INNER JOIN is used with an ON clause, CROSS JOIN is used otherwise.

In versions of MySQL prior to 5.0.1, parentheses in *table_references* were just omitted and all join operations were grouped to the left. In general, parentheses can be ignored in join expressions containing only inner join operations.

After removing parentheses and grouping operations to the left, the join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
   ON t1.a=t2.a
```

transforms into the expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
    ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables t1, t2, and t3 have the following state:

- Table t1 contains rows {1}, {2}

- Table t2 contains row {1,101}

- Table t3 contains row {101}

In this case, the first expression returns a result set including the rows {1,1,101,101}, {2,NULL,NULL,NULL}, whereas the second expression returns the rows {1,1,101,101}, {2,NULL,NULL,101}:

```
mysql> SELECT *
    -> FROM t1
    ->       LEFT JOIN
    ->       (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
    ->       ON t1.a=t2.a;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | NULL | NULL | NULL |
+------+------+------+------+

mysql> SELECT *
    -> FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
    ->       LEFT JOIN t3
    ->       ON t2.b=t3.b OR t2.b IS NULL;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | NULL | NULL |  101 |
+------+------+------+------+
```

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3.
```

For the given table states, the first expression returns rows {1,1,101,101}, {2,NULL,NULL,NULL}, whereas the second expression returns rows {1,1,101,101}, {2,NULL,NULL,101}:

```
mysql> SELECT *
    -> FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
+------+------+------+------+
| a    | a    | b    | b    |
```

```
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | NULL | NULL | NULL |
+------+------+------+------+
```

```
mysql> SELECT *
    -> FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | NULL | NULL |  101 |
+------+------+------+------+
```

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we can't ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```
(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)
```

is equivalent to the expression

```
t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)
```

for any tables `t1,t2,t3` and any condition `P` over attributes `t2.b` and `t3.b`.

Whenever the order of execution of the join operations in a join expression (*join_table*) is not from left to right, we talk about nested joins. Thus, the following queries:

```
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
  WHERE t1.a > 1

SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
  WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

the join tables:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3
```

are considered as nested. The nested join is formed in the first query with a left join operation, whereas in the second query it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. Yet for the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. (In our extended syntax the parentheses in (`t2`, `t3`) of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because `LEFT JOIN` and `ON` would play the role of the left and right delimiters for the expression (`t2,t3`).)

The preceding examples demonstrate these points:

• For join expressions involving only inner joins (and not outer joins), parentheses can be removed. You can remove parentheses and evaluate left to right (or in fact, you can evaluate the

tables in any order).

- The same is not true, in general, for outer joins. Removal of parentheses may change the result.

- The same also is not true, in general, for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Let's recall by what algorithmic schema the nested-loop join executes a query.

Suppose we have a join query over 3 tables `T1,T2,T3` of the form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
                  INNER JOIN T3 ON P2(T2,T3)
  WHERE P(T1,T2,T3).
```

Here, `P1(T1,T2)` and `P2(T3,T3)` are some join conditions (on expressions), whereas `P(t1,t2,t3)` is a condition over columns of tables `T1,T2,T3`.

The nested-loop join algorithm would execute this query in the following way:

```
FOR each row t1 in T1 {
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
          t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

The notation `t1||t2||t3` means "a row constructed by concatenating the columns of rows `t1`, `t2`, and `t3`." In some of the following examples, `NULL` where a row name appears means that `NULL` is used for each column of that row. For example, `t1||t2||NULL` means "a row constructed by concatenating the columns of rows `t1` and `t2`, and `NULL` for each column of `t3`."

Now let's consider a query with nested outer joins:

```
SELECT * FROM T1 LEFT JOIN
             (T2 LEFT JOIN T3 ON P2(T2,T3))
             ON P1(T1,T2)
  WHERE P(T1,T2,T3).
```

For this query we modify the nested-loop pattern to get:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f2=TRUE;
      f1=TRUE;
    }
    IF (!f2) {
      IF P(t1,t2,NULL) {
        t:=t1||t2||NULL; OUTPUT t;
      }
      f1=TRUE;
    }
```

```
   }
   IF (!f1) {
     IF P(t1,NULL,NULL) {
        t:=t1||NULL||NULL; OUTPUT t;
     }
   }
}
```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, then no match has been found for the current row of the outer table. In this case, the row is complemented by NULL values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In our example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

Note that for the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```
FOR each row t3 in T3 {
   FOR each row t2 in T2 such that P2(t2,t3) {
     FOR each row t1 in T1 such that P1(t1,t2) {
        IF P(t1,t2,t3) {
           t:=t1||t2||t3; OUTPUT t;
        }
     }
   }
}
```

For the queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer will evaluate two different nestings:

```
SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
   WHERE P(T1,T2,T3)
```

The nestings are these:

```
FOR each row t1 in T1 {
   BOOL f1:=FALSE;
   FOR each row t2 in T2 such that P1(t1,t2) {
     FOR each row t3 in T3 such that P2(t1,t3) {
        IF P(t1,t2,t3) {
           t:=t1||t2||t3; OUTPUT t;
        }
        f1:=TRUE
     }
   }
   IF (!f1) {
     IF P(t1,NULL,NULL) {
        t:=t1||NULL||NULL; OUTPUT t;
     }
   }
}
```

and

```
FOR each row t1 in T1 {
```

```
      BOOL f1:=FALSE;
      FOR each row t3 in T3 such that P2(t1,t3) {
        FOR each row t2 in T2 such that P1(t1,t2) {
          IF P(t1,t2,t3) {
             t:=t1||t2||t3; OUTPUT t;
          }
          f1:=TRUE
        }
      }
      IF (!f1) {
        IF P(t1,NULL,NULL) {
           t:=t1||NULL||NULL; OUTPUT t;
        }
      }
}
```

In both nestings, `T1` must be processed in the outer loop because it is used in an outer join. `T2` and `T3` are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, `T2` and `T3` can be processed in either order.

When discussing about nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called "pushed-down" conditions. Suppose our `WHERE` condition `P(T1,T2,T3)` can be represented by a conjunctive formula:

```
P(T1,T2,T2) = C1(T1) AND C2(T2) AND C3(T3).
```

In this case, MySQL actually uses the following nested-loop schema for the execution of the query with inner joins:

```
FOR each row t1 in T1 such that C1(t1) {
  FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2)  {
    FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
      IF P(t1,t2,t3) {
         t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

You see that each of the conjuncts `C1(T1)`, `C2(T2)`, `C3(T3)` are pushed out of the most inner loop to the most outer loop where it can be evaluated. If `C1(T1)` is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table `T1` passed to the inner loops. As a result, the execution time for query may improve immensely.

For a query with outer joins, the `WHERE` condition is to be checked only after it has been found out that the current row from the outer table has a match in the inner tables. Thus, the optimization with pushing condition out of the inner nested loops cannot be applied directly to queries with outer joins. Here we have to introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

For our example with outer joins with

```
P(T1,T2,T3)=C1(T1) AND C(T2) AND C3(T3)
```

the nested-loop schema using guarded pushed-down conditions looks like this:

```
FOR each row t1 in T1 such that C1(t1) {
  BOOL f1:=FALSE;
  FOR each row t2 in T2
      such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3
```

```
      such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
    IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
      t:=t1||t2||t3; OUTPUT t;
    }
    f2=TRUE;
    f1=TRUE;
  }
  IF (!f2) {
    IF (f1?TRUE:C2(t2) && P(t1,t2,NULL)) {
      t:=t1||t2||NULL; OUTPUT t;
    }
    f1=TRUE;
  }
}
IF (!f1 && P(t1,NULL,NULL)) {
    t:=t1||NULL||NULL; OUTPUT t;
  }
}
```

In general, pushed-down predicates can be extracted from join conditions such as `P1(T1,T2)` and `P(T2,T3)`. In this case, a pushed-down predicates are guarded also by a flag that prevents checking the predicate for the `NULL`-complemented row generated by the corresponding outer join operation.

Note that access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the `WHERE` condition. (We could use conditional key access in this case, but this technique is not employed yet in MySQL 5.0.)

7.2.11. How MySQL Simplifies Outer Joins

Table expressions in the `FROM` clause of a query are simplified in many cases.

At the parser stage, queries with right outer joins operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed according to the following rule:

```
(T1, ...) RIGHT JOIN (T2,...) ON P(T1,...,T2,...) =
(T2, ...) LEFT JOIN (T1,...) ON P(T1,...,T2,...).
```

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1,T2)` are replaced by the list `T1,T2, P(T1,T2)` being joined as a conjunct to the `WHERE` condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for join queries with outer join operation, it takes into consideration only the plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer options are limited because only such plans allow us to execute queries with outer joins operations by the nested loop schema.

Suppose we have a query of the form:

```
SELECT * T1 LEFT JOIN T2 ON P1(T1,T2)
  WHERE P(T1,T2) AND R(T2)
```

with `R(T2)` narrowing greatly the number of matching rows from table `T2`. If we executed the query as it is, the optimizer would have no other choice besides to access table `T1` before table `T2` that may lead to a very inefficient execution plan.

Fortunately, MySQL converts such a query into a query without an outer join operation if the `WHERE` condition is null-rejected. A condition is called null-rejected for an outer join operation if it evaluates to `FALSE` or to `UNKNOWN` for any `NULL`-complemented row built for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected:

```
T2.B IS NOT NULL,
T2.B > 3,
T2.C <= T1.C,
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected:

```
T2.B IS NULL,
T1.B < 3 OR T2.B IS NOT NULL,
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple. A condition is null-rejected in the following cases:

- If it is of the form `A IS NOT NULL`, where A is an attribute of any of the inner tables

- If it is a predicate containing a reference to an inner table that evaluates to `UNKNOWN` when one of its arguments is `NULL`

- If it is a conjunction containing a null-rejected condition as a conjunct

- If it is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                 LEFT JOIN T3 ON T3.B=T1.B
  WHERE T3.C > 0
```

the `WHERE` condition is null-rejected for the second outer join operation but is not null-rejected for the first one.

If the `WHERE` condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, the preceding query is replaced with the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                 INNER JOIN T3 ON T3.B=T1.B
  WHERE T3.C > 0
```

For the original query, the optimizer would evaluate plans compatible with only one access order T1,T2,T3. For the replacing query, it additionally considers the access sequence T3,T1,T2.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                 LEFT JOIN T3 ON T3.B=T2.B
  WHERE T3.C > 0
```

will be first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
```

```
                    INNER JOIN T3 ON T3.B=T2.B
  WHERE T3.C > 0
```

which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
  WHERE T3.C > 0 AND T3.B=T2.B
```

Now the remaining outer join operation can be replaced by an inner join, too, because the condition T3.B=T2.B is null-rejected and we get a query without outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
  WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes we succeed in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
              (T2 LEFT JOIN T3 ON T3.B=T2.B)
              ON T2.A=T1.A
  WHERE T3.C > 0
```

is converted to:

```
SELECT * FROM T1 LEFT JOIN
              (T2 INNER JOIN T3 ON T3.B=T2.B)
              ON T2.A=T1.A
  WHERE T3.C > 0,
```

That can be rewritten only to the form still containing the embedding outer join operation:

```
SELECT * FROM T1 LEFT JOIN
              (T2,T3)
              ON (T2.A=T1.A AND T3.B=T2.B)
  WHERE T3.C > 0.
```

When trying to convert an embedded outer join operation in a query, we have to take into account the join condition for the embedding outer join together with the WHERE condition. In the query:

```
SELECT * FROM T1 LEFT JOIN
              (T2 LEFT JOIN T3 ON T3.B=T2.B)
              ON T2.A=T1.A AND T3.C=T1.C
  WHERE T3.D > 0 OR T1.D > 0
```

the WHERE condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join T2.A=T1.A AND T3.C=T1.C is null-rejected. So the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
              (T2, T3)
              ON T2.A=T1.A AND T3.C=T1.C AND T3.B=T2.B
  WHERE T3.D > 0 OR T1.D > 0
```

The algorithm that converts outer join operations into inner joins was implemented in full measure, as it has been described here, in MySQL 5.0.1. MySQL 4.1 performs only some simple conversions.

7.2.12. How MySQL Optimizes `ORDER BY`

In some cases, MySQL can use an index to satisfy an `ORDER BY` clause without doing any extra sorting.

The index can also be used even if the `ORDER BY` doesn't match the index exactly, as long as all the unused index parts and all the extra are `ORDER BY` columns are constants in the `WHERE` clause. The following queries use the index to resolve the `ORDER BY` part:

```
SELECT * FROM t1 ORDER BY key_part1,key_part2,... ;
SELECT * FROM t1 WHERE key_part1=constant ORDER BY key_part2;
SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 DESC;
SELECT * FROM t1
    WHERE key_part1=1 ORDER BY key_part1 DESC, key_part2 DESC;
```

In some cases, MySQL *cannot* use indexes to resolve the `ORDER BY`, although it still uses indexes to find the rows that match the `WHERE` clause. These cases include the following:

- You use `ORDER BY` on different keys:

  ```
  SELECT * FROM t1 ORDER BY key1, key2;
  ```

- You use `ORDER BY` on non-consecutive key parts:

  ```
  SELECT * FROM t1 WHERE key2=constant ORDER BY key_part2;
  ```

- You mix `ASC` and `DESC`:

  ```
  SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 ASC;
  ```

- The key used to fetch the rows is not the same as the one used in the `ORDER BY`:

  ```
  SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
  ```

- You are joining many tables, and the columns in the `ORDER BY` are not all from the first non-constant table that is used to retrieve rows. (This is the first table in the `EXPLAIN` output that doesn't have a `const` join type.)

- You have different `ORDER BY` and `GROUP BY` expressions.

- The type of table index used doesn't store rows in order. For example, this is true for a `HASH` index in a `HEAP` table.

With `EXPLAIN SELECT ... ORDER BY`, you can check whether MySQL can use indexes to resolve the query. It cannot if you see `Using filesort` in the `Extra` column. See Section 7.2.1, "EXPLAIN Syntax (Get Information About a `SELECT`)".

In those cases where MySQL must sort the result, it uses the following `filesort` algorithm before MySQL 4.1:

1. Read all rows according to key or by table scanning. Rows that don't match the `WHERE` clause are skipped.

2. For each row, store a pair of values in a buffer (the sort key and the row pointer). The size of the buffer is the value of the `sort_buffer_size` system variable.

3. When the buffer gets full, run a qsort (quicksort) on it and store the result in a temporary file. Save a pointer to the sorted block. (If all pairs fit into the sort buffer, no temporary file is created.)

4. Repeat the preceding steps until all rows have been read.

5. Do a multi-merge of up to `MERGEBUFF` (7) regions to one block in another temporary file. Repeat until all blocks from the first file are in the second file.

6. Repeat the following until there are fewer than `MERGEBUFF2` (15) blocks left.

7. On the last multi-merge, only the pointer to the row (the last part of the sort key) is written to a result file.

8. Read the rows in sorted order by using the row pointers in the result file. To optimize this, we read in a big block of row pointers, sort them, and use them to read the rows in sorted order into a row buffer. The size of the buffer is the value of the `read_rnd_buffer_size` system variable. The code for this step is in the `sql/records.cc` source file.

One problem with this approach is that it reads rows twice: One time when evaluating the `WHERE` clause, and again after sorting the pair values. And even if the rows were accessed successively the first time (for example, if a table scan is done), the second time they are accessed randomly. (The sort keys are ordered, but the row positions are not.)

In MySQL 4.1 and up, a `filesort` optimization is used that records not only the sort key value and row position, but also the columns required for the query. This avoids reading the rows twice. The modified `filesort` algorithm works like this:

1. Read the rows that match the `WHERE` clause, as before.

2. For each row, record a tuple of values consisting of the sort key value and row position, and also the columns required for the query.

3. Sort the tuples by sort key value

4. Retrieve the rows in sorted order, but read the required columns directly from the sorted tuples rather than by accessing the table a second time.

Using the modified `filesort` algorithm, the tuples are longer than the pairs used in the original method, and fewer of them fit in the sort buffer (the size of which is given by `sort_buffer_size`). As a result, it is possible for the extra I/O to make the modified approach slower, not faster. To avoid a slowdown, the optimization is used only if the total size of the extra columns in the sort tuple does not exceed the value of the `max_length_for_sort_data` system variable. (A symptom of setting the value of this variable too high is that you should see high disk activity and low CPU activity.)

If you want to increase `ORDER BY` speed, first see whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, you can try the following strategies:

• Increase the size of the `sort_buffer_size` variable.

• Increase the size of the `read_rnd_buffer_size` variable.

• Change `tmpdir` to point to a dedicated filesystem with lots of empty space. If you use MySQL 4.1 or later, this option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters ('`:`') on Unix and semicolon characters ('`;`') on Windows, NetWare, and OS/2. You can use this feature to spread the load across several directories. *Note:* The paths should be for directories in filesystems that are located on different *physical* disks, not different partitions of the same disk.

By default, MySQL sorts all `GROUP BY col1, col2, ...` queries as if you specified `ORDER BY col1, col2, ...` in the query as well. If you include an `ORDER BY` clause explicitly that contains the same column list, MySQL optimizes it away without any speed penalty, although the

sorting still occurs. If a query includes `GROUP BY` but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying `ORDER BY NULL`. For example:

```
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```

7.2.13. How MySQL Optimizes `GROUP BY`

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and to avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and the index stores its keys in order (for example, this is a B-Tree index, and not a HASH index). Whether usage of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query via index access, as detailed in the following sections. In the first method, the grouping operation is applied together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

7.2.13.1. Loose index scan

The most efficient way is when the index is used to directly retrieve the group fields. With this access method, MySQL uses the property of some index types (for example, B-Trees) that the keys are ordered. This property allows use of lookup groups in an index without having to consider all keys in the index that satisfy all `WHERE` conditions. Since this access method considers only a fraction of the keys in an index, it is called "loose index scan." When there is no `WHERE` clause, a loose index scan reads as many keys as the number of groups, which may be a much smaller number than all keys. If the `WHERE` clause contains range predicates (described in Section 7.2.1, "EXPLAIN Syntax (Get Information About a `SELECT`)", under the `range` join type), a loose index scan looks up the first key of each group that satisfies the range conditions, and again reads the least possible number of keys. This is possible under the following conditions:

- The query is over a single table.

- The `GROUP BY` includes the first consecutive parts of the index (if instead of `GROUP BY`, the query has a `DISTINCT` clause, then all distinct attributes refer to the beginning of the index).

- The only aggregate functions used (if any) are `MIN()` and `MAX()`, and all of them refer to the same column.

- Any other index parts than the ones from `GROUP BY` referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of `MIN()` or `MAX()` functions.

The `EXPLAIN` output for such queries shows `Using index for group-by` in the `Extra` column.

The following queries provide several examples that fall into this category, assuming there is an index `idx(c1, c2, c3)` on table `t1(c1,c2,c3,c4)`:

```
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;
```

The following queries cannot be executed with this quick select method, for the reasons given:

- There are other aggregate function than `MIN()` or `MAX()`:

  ```
  SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
  ```

- The fields in `GROUP BY` do not refer to the beginning of the index:

  ```
  SELECT c1,c2 FROM t1 GROUP BY c2, c3;
  ```

- The query refers to a key part that is after the `GROUP BY` parts, and for which there is no equality with a constant:

  ```
  SELECT c1,c3 FROM t1 GROUP BY c1, c2;
  ```

7.2.13.2. Tight index scan

A tight index scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a loose index scan are not met, it is still possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Since this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, we term it a "tight index scan." Notice that with a tight index scan, the grouping operation is performed after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that for all columns in a query referring to key parts before or in between the `GROUP BY` key parts, there is a constant equality condition. The constants from the equality conditions fill in the "gaps" in the search keys so that it is possible to form complete prefixes of the index. Then these index prefixes can be used for index lookups. If we require sorting of the `GROUP BY` result, and it is possible to form search keys that are prefixes of the index, MySQL also avoids sorting because searching with prefixes in an ordered index retrieves all keys in order.

The following queries do not work with the first method above, but still work with the second index access method (assuming we have the aforementioned index `idx` on table `t1`):

- There is a "gap" in `GROUP BY`, but it is covered by the condition (c2 = 'a').

  ```
  SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
  ```

- `GROUP BY` does not begin from the first key part, but there is a condition that provides a constant for that key part:

  ```
  SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
  ```

7.2.14. How MySQL Optimizes `LIMIT`

In some cases, MySQL handles a query differently when you are using `LIMIT row_count` and not using `HAVING`:

- If you are selecting only a few rows with `LIMIT`, MySQL uses indexes in some cases when nor-

mally it would prefer to do a full table scan.

- If you use LIMIT *row_count* with ORDER BY, MySQL ends the sorting as soon as it has found the first *row_count* rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the LIMIT clause must be selected, and most or all of them must be sorted, before it can be ascertained that the first *row_count* rows have been found. In either case, once the rows have been found, there is no need to sort any remainder of the result set, and MySQL does not do so.

- When combining LIMIT *row_count* with DISTINCT, MySQL stops as soon as it finds *row_count* unique rows.

- In some cases, a GROUP BY can be resolved by reading the key in order (or doing a sort on the key) and then calculating summaries until the key value changes. In this case, LIMIT *row_count* does not calculate any unnecessary GROUP BY values.

- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using SQL_CALC_FOUND_ROWS.

- LIMIT 0 always quickly returns an empty set. This is useful to check the query or to get the column types of the result columns.

- When the server uses temporary tables to resolve the query, the LIMIT *row_count* is used to calculate how much space is required.

7.2.15. How to Avoid Table Scans

The output from EXPLAIN shows ALL in the type column when MySQL uses a table scan to resolve a query. This usually happens under the following conditions:

- The table is so small that it's faster to do a table scan than a key lookup. This is a common case for tables with fewer than 10 rows and a short row length.

- There are no usable restrictions in the ON or WHERE clause for indexed columns.

- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See Section 7.2.4, "How MySQL Optimizes WHERE Clauses".

- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably does a lot of key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use ANALYZE TABLE *tbl_name* to update the key distributions for the scanned table. See Section 13.5.2.1, "ANALYZE TABLE Syntax".

- Use FORCE INDEX for the scanned table to tell MySQL that table scans are very expensive compared to using the given index. See Section 13.2.7, "SELECT Syntax".

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

- Start mysqld with the --max-seeks-for-key=1000 option or use SET max_seeks_for_key=1000 to tell the optimizer to assume that no key scan causes more

than 1,000 key seeks. See Section 5.3.3, "Server System Variables".

7.2.16. Speed of `INSERT` Statements

The time to insert a record is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)

- Sending query to server: (2)

- Parsing query: (2)

- Inserting record: (1 x size of record)

- Inserting indexes: (1 x number of indexes)

- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by log N, assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use `INSERT` statements with multiple `VALUES` lists to insert several rows at a time. This is much faster (many times faster in some cases) than using separate single-row `INSERT` statements. If you are adding data to a non-empty table, you may tune the `bulk_insert_buffer_size` variable to make it even faster. See Section 5.3.3, "Server System Variables".

- If you are inserting a lot of rows from different clients, you can get higher speed by using the `INSERT DELAYED` statement. See Section 13.2.4, "`INSERT` Syntax".

- With `MyISAM` tables you can insert rows at the same time that `SELECT` statements are running if there are no deleted rows in the tables.

- When loading a table from a text file, use `LOAD DATA INFILE`. This is usually 20 times faster than using a lot of `INSERT` statements. See Section 13.2.5, "`LOAD DATA INFILE` Syntax".

- With some extra work, it is possible to make `LOAD DATA INFILE` run even faster when the table has many indexes. Use the following procedure:

  1. Optionally create the table with `CREATE TABLE`.

  2. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

  3. Use `myisamchk --keys-used=0 -rq /path/to/db/tbl_name`. This removes all use of indexes for the table.

  4. Insert data into the table with `LOAD DATA INFILE`. This does not update any indexes and therefore is very fast.

  5. If you are going to only read the table in the future, use `myisampack` to make it smaller. See Section 14.1.3.3, "Compressed Table Characteristics".

  6. Re-create the indexes with `myisamchk -r -q /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster because it

avoids lots of disk seeks. The resulting index tree is also perfectly balanced.

7. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

Note that `LOAD DATA INFILE` also performs the preceding optimization if you insert into an empty `MyISAM` table; the main difference is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the `LOAD DATA INFILE` statement.

As of MySQL 4.0, you can also use `ALTER TABLE` *tbl_name* `DISABLE KEYS` instead of `myisamchk --keys-used=0 -rq` */path/to/db/tbl_name* and `ALTER TABLE` *tbl_name* `ENABLE KEYS` instead of `myisamchk -r -q` */path/to/db/tbl_name*. This way you can also skip the `FLUSH TABLES` steps.

- You can speed up `INSERT` operations that are done with multiple statements by locking your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
UNLOCK TABLES;
```

A performance benefit occurs because the index buffer is flushed to disk only once, after all `INSERT` statements have completed. Normally there would be as many index buffer flushes as there are different `INSERT` statements. Explicit locking statements are not needed if you can insert all rows with a single statement.

For transactional tables, you should use `BEGIN/COMMIT` instead of `LOCK TABLES` to get a speedup.

Locking also lowers the total time of multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. For example:

```
Connection 1 does 1000 inserts
Connections 2, 3, and 4 do 1 insert
Connection 5 does 1000 inserts
```

If you don't use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

`INSERT`, `UPDATE`, and `DELETE` operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five inserts or updates in a row. If you do very many inserts in a row, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (about each 1,000 rows) to allow other threads access to the table. This would still result in a nice performance gain.

`INSERT` is still much slower for loading data than `LOAD DATA INFILE`, even when using the strategies just outlined.

- To get some more speed for `MyISAM` tables, for both `LOAD DATA INFILE` and `INSERT`, enlarge the key cache by increasing the `key_buffer_size` system variable. See Section 7.5.2, "Tuning Server Parameters".

7.2.17. Speed of `UPDATE` Statements

Update statements are optimized as a `SELECT` query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed does not get updated.

Also, another way to get fast updates is to delay updates and then do many updates in a row later. Doing many updates in a row is much quicker than doing one at a time if you lock the table.

Note that for a `MyISAM` table that uses dynamic record format, updating a record to a longer total length may split the record. If you do this often, it is very important to use `OPTIMIZE TABLE` occasionally. See Section 13.5.2.5, "`OPTIMIZE TABLE` Syntax".

7.2.18. Speed of `DELETE` Statements

The time to delete individual records is exactly proportional to the number of indexes. To delete records more quickly, you can increase the size of the key cache. See Section 7.5.2, "Tuning Server Parameters".

If you want to delete all rows in the table, use `TRUNCATE TABLE tbl_name` rather than `DELETE FROM tbl_name`. See Section 13.2.9, "`TRUNCATE` Syntax".

7.2.19. Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- Use persistent connections to the database to avoid connection overhead. If you can't use persistent connections and you are initiating many new connections to the database, you may want to change the value of the `thread_cache_size` variable. See Section 7.5.2, "Tuning Server Parameters".

- Always check whether all your queries really use the indexes you have created in the tables. In MySQL, you can do this with the `EXPLAIN` statement. See Section 7.2.1, "`EXPLAIN` Syntax (Get Information About a `SELECT`)".

- Try to avoid complex `SELECT` queries on `MyISAM` tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.

- With `MyISAM` tables that have no deleted rows, you can insert rows at the end at the same time that another query is reading from the table. If this is important for you, you should consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` after you have deleted a lot of rows. See Section 14.1, "The `MyISAM` Storage Engine".

- To fix any compression issues that may have occurred with `ARCHIVE` tables you can always do an `OPTIMIZE TABLE`. See Section 14.7, "The `ARCHIVE` Storage Engine".

- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you mostly retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.

- In some cases, it may make sense to introduce a column that is "hashed" based on information from other columns. If this column is short and reasonably unique, it may be much faster than a big index on many columns. In MySQL, it's very easy to use this extra column:

```
SELECT * FROM tbl_name
    WHERE hash_col=MD5(CONCAT(col1,col2))
    AND col1='constant' AND col2='constant';
```

- For `MyISAM` tables that change a lot, you should try to avoid all variable-length columns (`VARCHAR`, `BLOB`, and `TEXT`). The table uses dynamic record format if it includes even a single variable-length column. See Chapter 14, *MySQL Storage Engines and Table Types*.

- It's normally not useful to split a table into different tables just because the rows get "big." To access a row, the biggest performance hit is the disk seek to find the first byte of the row. After finding the data, most modern disks can read the whole row fast enough for most applications. The only cases where it really matters to split up a table is if it's a `MyISAM` table with dynamic

record format (see above) that you can change to a fixed record size, or if you very often need to scan the table but do not need most of the columns. See Chapter 14, *MySQL Storage Engines and Table Types*.

- If you very often need to calculate results such as counts based on information from a lot of rows, it's probably much better to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is really important when you use MySQL storage engines such as `MyISAM` and `ISAM` that have only table-level locking (multiple readers / single writers). This also gives better performance with most databases, because the row locking manager in this case has less to do.

- If you need to collect statistics from large log tables, use summary tables instead of scanning the entire log table. Maintaining the summaries should be much faster than trying to calculate statistics "live." It's much faster to regenerate new summary tables from the logs when things change (depending on business decisions) than to have to change the running application!

- If possible, you should classify reports as "live" or "statistical," where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.

- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL needs to do and improves the insert speed.

- In some cases, it's convenient to pack and store data into a `BLOB` column. In this case, you must add some extra code in your application to pack and unpack information in the `BLOB` values, but this may save a lot of accesses at some stage. This is practical when you have data that doesn't conform to a rows-and-columns table structure.

- Normally, you should try to keep all data non-redundant (what is called "third normal form" in database theory). However, do not be afraid to duplicate information or create summary tables if necessary to gain more speed.

- Stored procedures or UDFs (user-defined functions) may be a good way to get more performance for some tasks. However, if you use a database system that does not support these capabilities, you should always have another way to perform the same tasks, even if the alternative method is slower.

- You can always gain something by caching queries or answers in your application and then performing many inserts or updates together. If your database supports table locks (like MySQL and Oracle), this should help to ensure that the index cache is only flushed once after all updates.

- Use `INSERT DELAYED` when you do not need to know when your data is written. This speeds things up because many records can be written with a single disk write.

- Use `INSERT LOW_PRIORITY` when you want to give `SELECT` statements higher priority than your inserts.

- Use `SELECT HIGH_PRIORITY` to get retrievals that jump the queue. That is, the `SELECT` is done even if there is another client waiting to do a write.

- Use multiple-row `INSERT` statements to store many rows with one SQL statement (many SQL servers support this).

- Use `LOAD DATA INFILE` to load large amounts of data. This is faster than using `INSERT` statements.

- Use `AUTO_INCREMENT` columns to generate unique values.

- Use `OPTIMIZE TABLE` once in a while to avoid fragmentation with `MyISAM` tables when using a dynamic table format. See Section 14.1.3, "`MyISAM` Table Storage Formats".

- Use `HEAP` tables when possible to get more speed. See Chapter 14, *MySQL Storage Engines and Table Types*.

- When using a normal Web server setup, images should be stored as files. That is, store only a file reference in the database. The main reason for this is that a normal Web server is much better at caching files than database contents, so it's much easier to get a fast system if you are using files.

- Use in-memory tables for non-critical data that is accessed often, such as information about the last displayed banner for users who don't have cookies enabled in their Web browser.

- Columns with identical information in different tables should be declared to have identical data types. Before MySQL 3.23, you get slow joins otherwise.

  Try to keep column names simple. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, you should keep them shorter than 18 characters.

- If you need really high speed, you should take a look at the low-level interfaces for data storage that the different SQL servers support! For example, by accessing the MySQL `MyISAM` storage engine directly, you could get a speed increase of two to five times compared to using the SQL interface. To be able to do this, the data must be on the same server as the application, and usually it should only be accessed by one process (because external file locking is really slow). One could eliminate these problems by introducing low-level `MyISAM` commands in the MySQL server (this could be one easy way to get more performance if needed). By carefully designing the database interface, it should be quite easy to support this types of optimization.

- If you are using numerical data, it's faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you don't have to parse your text files to find line and column boundaries.

- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replication servers to split up the load. To avoid slowing down the master while making backups, you can make backups using a slave server. See Chapter 6, *Replication in MySQL*.

- Declaring a `MyISAM` table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you should ensure that they are okay by running the server with the `--myisam-recover` option, or by running `myisamchk` before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)

7.3. Locking Issues

7.3.1. Locking Methods

Currently, MySQL supports table-level locking for `ISAM`, `MyISAM`, and `MEMORY` (`HEAP`) tables, page-level locking for `BDB` tables, and row-level locking for `InnoDB` tables.

In many cases, you can make an educated guess about which locking type is best for an application, but generally it's very hard to say that a given lock type is better than another. Everything depends on the application and different parts of an application may require different lock types.

To decide whether you want to use a storage engine with row-level locking, you should look at what your application does and what mix of select and update statements it uses. For example, most Web applications do lots of selects, very few deletes, updates based mainly on key values, and inserts into

some specific tables. The base MySQL `MyISAM` setup is very well tuned for this.

Table locking in MySQL is deadlock-free for storage engines that use table-level locking. Deadlock avoidance is managed by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order.

The table-locking method MySQL uses for `WRITE` locks works as follows:

- If there are no locks on the table, put a write lock on it.

- Otherwise, put the lock request in the write lock queue.

The table-locking method MySQL uses for `READ` locks works as follows:

- If there are no write locks on the table, put a read lock on it.

- Otherwise, put the lock request in the read lock queue.

When a lock is released, the lock is made available to the threads in the write lock queue, then to the threads in the read lock queue.

This means that if you have many updates for a table, `SELECT` statements wait until there are no more updates.

Starting in MySQL 3.23.33, you can analyze the table lock contention on your system by checking the `Table_locks_waited` and `Table_locks_immediate` status variables:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----------------------+---------+
| Variable_name         | Value   |
+-----------------------+---------+
| Table_locks_immediate | 1151552 |
| Table_locks_waited    | 15324   |
+-----------------------+---------+
```

As of MySQL 3.23.7 (3.23.25 for Windows), you can freely mix concurrent `INSERT` and `SELECT` statements for a `MyISAM` table without locks if the `INSERT` statements are non-conflicting. That is, you can insert rows into a `MyISAM` table at the same time other clients are reading from it. No conflict occurs if the data file contains no free blocks in the middle, because in that case, records always are inserted at the end of the data file. (Holes can result from rows having been deleted from or updated in the middle of the table.) If there are holes, concurrent inserts are re-enabled automatically when all holes have been filled with new data.

If you want to do many `INSERT` and `SELECT` operations on a table when concurrent inserts are not possible, you can insert rows in a temporary table and update the real table with the records from the temporary table once in a while. This can be done with the following code:

```
mysql> LOCK TABLES real_table WRITE, insert_table WRITE;
mysql> INSERT INTO real_table SELECT * FROM insert_table;
mysql> TRUNCATE TABLE insert_table;
mysql> UNLOCK TABLES;
```

`InnoDB` uses row locks and `BDB` uses page locks. For the `InnoDB` and `BDB` storage engines, deadlock is possible. This is because `InnoDB` automatically acquires row locks and `BDB` acquires page locks during the processing of SQL statements, not at the start of the transaction.

Advantages of row-level locking:

- Fewer lock conflicts when accessing different rows in many threads.

- Fewer changes for rollbacks.

- Makes it possible to lock a single row a long time.

Disadvantages of row-level locking:

- Takes more memory than page-level or table-level locks.

- Is slower than page-level or table-level locks when used on a large part of the table because you must acquire many more locks.

- Is definitely much worse than other locks if you often do `GROUP BY` operations on a large part of the data or if you often must scan the entire table.

- With higher-level locks, you can also more easily support locks of different types to tune the application, because the lock overhead is less than for row-level locks.

Table locks are superior to page-level or row-level locks in the following cases:

- Most statements for the table are reads.

- Read and updates on strict keys, where you update or delete a row that can be fetched with a single key read:

  ```
  UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
  DELETE FROM tbl_name WHERE unique_key_col=key_value;
  ```

- `SELECT` combined with concurrent `INSERT` statements, and very few `UPDATE` and `DELETE` statements.

- Many scans or `GROUP BY` operations on the entire table without any writers.

Options other than row-level or page-level locking:

Versioning (such as we use in MySQL for concurrent inserts) where you can have one writer at the same time as many readers. This means that the database/table supports different views for the data depending on when you started to access it. Other names for this are time travel, copy on write, or copy on demand.

Copy on demand is in many cases much better than page-level or row-level locking. However, the worst case does use much more memory than when using normal locks.

Instead of using row-level locks, you can use application-level locks, such as `GET_LOCK()` and `RELEASE_LOCK()` in MySQL. These are advisory locks, so they work only in well-behaved applications.

7.3.2. **Table Locking Issues**

To achieve a very high lock speed, MySQL uses table locking (instead of page, row, or column locking) for all storage engines except `InnoDB` and `BDB`.

For `InnoDB` and `BDB` tables, MySQL uses only table locking if you explicitly lock the table with `LOCK TABLES`. For these table types, we recommend that you not use `LOCK TABLES` at all, because `InnoDB` uses automatic row-level locking and `BDB` uses page-level locking to ensure transaction isolation.

For large tables, table locking is much better than row locking for most applications, but there are some pitfalls.

Table locking enables many threads to read from a table at the same time, but if a thread wants to write to a table, it must first get exclusive access. During the update, all other threads that want to access this particular table must wait until the update is done.

Table updates normally are considered to be more important than table retrievals, so they are given higher priority. This should ensure that updates to a table are not "starved" even if there is heavy SELECT activity for the table.

Table locking causes problems in cases such as when a thread is waiting because the disk is full and free space needs to become available before the thread can proceed. In this case, all threads that want to access the problem table are also put in a waiting state until more disk space is made available.

Table locking is also disadvantageous under the following scenario:

- A client issues a SELECT that takes a long time to run.

- Another client then issues an UPDATE on the same table. This client waits until the SELECT is finished.

- Another client issues another SELECT statement on the same table. Because UPDATE has higher priority than SELECT, this SELECT waits for the UPDATE to finish. It also waits for the first SELECT to finish!

The following list describes some ways to avoid or reduce contention caused by table locking:

- Try to get the SELECT statements to run faster. You might have to create some summary tables to do this.

- Start mysqld with --low-priority-updates. This gives all statements that update (modify) a table lower priority than SELECT statements. In this case, the second SELECT statement in the preceding scenario would execute before the INSERT statement, and would not need to wait for the first SELECT to finish.

- You can specify that all updates issued in a specific connection should be done with low priority by using the SET LOW_PRIORITY_UPDATES=1 statement. See Section 13.5.3, "SET Syntax".

- You can give a specific INSERT, UPDATE, or DELETE statement lower priority with the LOW_PRIORITY attribute.

- You can give a specific SELECT statement higher priority with the HIGH_PRIORITY attribute. See Section 13.2.7, "SELECT Syntax".

- Starting from MySQL 3.23.7, you can start mysqld with a low value for the max_write_lock_count system variable to force MySQL to temporarily elevate the priority of all SELECT statements that are waiting for a table after a specific number of inserts to the table occur. This allows READ locks after a certain number of WRITE locks.

- If you have problems with INSERT combined with SELECT, switch to using MyISAM tables, which support concurrent SELECT and INSERT statements.

- If you mix inserts and deletes on the same table, INSERT DELAYED may be of great help. See Section 13.2.4.2, "INSERT DELAYED Syntax".

- If you have problems with mixed SELECT and DELETE statements, the LIMIT option to DELETE may help. See Section 13.2.1, "DELETE Syntax".

- Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See Section 13.2.7, "`SELECT` Syntax".

- You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

Here are some tips about table locking in MySQL:

- Concurrent users are not a problem if you don't mix updates with selects that need to examine many rows in the same table.

- You can use `LOCK TABLES` to speed up things (many updates within a single lock is much faster than updates without locks). Splitting table contents into separate tables may also help.

- If you encounter speed problems with table locks in MySQL, you may be able to improve performance by converting some of your tables to `InnoDB` or `BDB` tables. See Chapter 15, *The InnoDB Storage Engine*. See Section 14.4, "The `BDB` (`BerkeleyDB`) Storage Engine".

7.4. Optimizing Database Structure

7.4.1. Design Choices

MySQL keeps row data and index data in separate files. Many (almost all) other databases mix row and index data in the same file. We believe that the MySQL choice is better for a very wide range of modern systems.

Another way to store the row data is to keep the information for each column in a separate area (examples are SDBM and Focus). This causes a performance hit for every query that accesses more than one column. Because this degenerates so quickly when more than one column is accessed, we believe that this model is not good for general-purpose databases.

The more common case is that the index and data are stored together (as in Oracle/Sybase, et al). In this case, you find the row information at the leaf page of the index. The good thing with this layout is that it, in many cases, depending on how well the index is cached, saves a disk read. The bad things with this layout are:

- Table scanning is much slower because you have to read through the indexes to get at the data.

- You can't use only the index table to retrieve data for a query.

- You use more space because you must duplicate indexes from the nodes (you can't store the row in the nodes).

- Deletes degenerate the table over time (because indexes in nodes are usually not updated on delete).

- It's harder to cache only the index data.

7.4.2. Make Your Data as Small as Possible

One of the most basic optimizations is to design your tables to take as little space on the disk as possible. This can give huge improvements because disk reads are faster, and smaller tables normally require less main memory while their contents are being actively processed during query execution. Indexing also is a lesser resource burden if done on smaller columns.

MySQL supports a lot of different table types and row formats. For each table, you can decide which storage/index method to use. Choosing the right table format for your application may give you a big performance gain. See Chapter 14, *MySQL Storage Engines and Table Types*.

You can get better performance on a table and minimize storage space using the techniques listed here:

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory.

- Use the smaller integer types if possible to get smaller tables. For example, `MEDIUMINT` is often better than `INT`.

- Declare columns to be `NOT NULL` if possible. It makes everything faster and you save one bit per column. If you really need `NULL` in your application, you should definitely use it. Just avoid having it on all columns by default.

- For `MyISAM` tables, if you don't have any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB` columns), a fixed-size record format is used. This is faster but unfortunately may waste some space. See Section 14.1.3, "`MyISAM` Table Storage Formats". You can hint that you want to have fixed length rows even if you have `VARCHAR` columns with the `CREATE` option `ROW_FORMAT=fixed`.

- Starting with MySQL/InnoDB 5.0.3, `InnoDB` tables use a more compact storage format. In earlier versions of MySQL, InnoDB records contain some redundant information, such as the number of columns and the length of each column, even for fixed-size columns. By default, tables are created in the compact format (`ROW_FORMAT=COMPACT`). If you wish to downgrade to older versions of MySQL/InnoDB, you can request the old format with `ROW_FORMAT=REDUNDANT`.

  The compact InnoDB format also changes the way how `CHAR` columns containing UTF-8 data are stored. In the `ROW_FORMAT=REDUNDANT` format, a UTF-8 `CHAR(`n`)` occupies $3*n$ bytes, given that the maximum length of a UTF-8 encoded character is 3 bytes. Since many languages can be written mostly with single-byte UTF-8 characters, a fixed storage length often wastes space. The `ROW_FORMAT=COMPACT` format allocates a variable amount of $n..3*n$ bytes for these columns by stripping trailing spaces if necessary. The minimum storage length is kept as n bytes in order to facilitate in-place updates in typical cases.

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient.

- Create only the indexes that you really need. Indexes are good for retrieval but bad when you need to store things fast. If you mostly access a table by searching on a combination of columns, make an index on them. The first index part should be the most used column. If you are *always* using many columns, you should use the column with more duplicates first to get better compression of the index.

- If it's very likely that a column has a unique prefix on the first number of characters, it's better to index only this prefix. MySQL supports an index on the leftmost part of a character column. Shorter indexes are faster not only because they take less disk space, but also because they give you more hits in the index cache and thus fewer disk seeks. See Section 7.5.2, "Tuning Server Parameters".

- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.

7.4.3. Column Indexes

All MySQL column types can be indexed. Use of indexes on the relevant columns is the best way to improve the performance of `SELECT` operations.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See Chapter 14, *MySQL Storage Engines and Table Types*. All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

With `col_name(length)` syntax in an index specification, you can create an index that uses only the first `length` characters of a `CHAR` or `VARCHAR` column. Indexing only a prefix of column values like this can make the index file much smaller.

The `MyISAM` and (as of MySQL 4.0.14) `InnoDB` storage engines also support indexing on `BLOB` and `TEXT` columns. When indexing a `BLOB` or `TEXT` column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 255 bytes long (or 1000 bytes for `MyISAM` and `InnoDB` tables as of MySQL 4.1.2). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters. Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

As of MySQL 3.23.23, you can also create `FULLTEXT` indexes. They are used for full-text searches. Only the `MyISAM` table type supports `FULLTEXT` indexes and only for `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column and partial (prefix) indexing is not supported. See Section 12.7, "Full-Text Search Functions" for details.

As of MySQL 4.1.0, you can create indexes on spatial column types. Currently, spatial types are supported only by the `MyISAM` storage engine. Spatial indexes use R-trees.

The `MEMORY` (`HEAP`) storage engine uses hash indexes by default. It also supports B-tree indexes as of MySQL 4.1.0.

7.4.4. Multiple-Column Indexes

MySQL can create indexes on multiple columns. An index may consist of up to 15 columns. For certain column types, you can index a prefix of the column (see Section 7.4.3, "Column Indexes").

A multiple-column index can be considered a sorted array containing values that are created by concatenating the values of the indexed columns.

MySQL uses multiple-column indexes in such a way that queries are fast when you specify a known quantity for the first column of the index in a `WHERE` clause, even if you don't specify values for the other columns.

Suppose that a table has the following specification:

```
CREATE TABLE test (
    id INT NOT NULL,
    last_name CHAR(30) NOT NULL,
    first_name CHAR(30) NOT NULL,
    PRIMARY KEY (id),
    INDEX name (last_name,first_name));
```

The `name` index is an index over `last_name` and `first_name`. The index can be used for queries that specify values in a known range for `last_name`, or for both `last_name` and `first_name`. Therefore, the `name` index is used in the following queries:

```
SELECT * FROM test WHERE last_name='Widenius';

SELECT * FROM test
    WHERE last_name='Widenius' AND first_name='Michael';

SELECT * FROM test
```

```
    WHERE last_name='Widenius'
    AND (first_name='Michael' OR first_name='Monty');

SELECT * FROM test
    WHERE last_name='Widenius'
    AND first_name >='M' AND first_name < 'N';
```

However, the `name` index is *not* used in the following queries:

```
SELECT * FROM test WHERE first_name='Michael';

SELECT * FROM test
    WHERE last_name='Widenius' OR first_name='Michael';
```

The manner in which MySQL uses indexes to improve query performance is discussed further in the next section.

7.4.5. How MySQL Uses Indexes

Indexes are used to find rows with specific column values fast. Without an index, MySQL has to start with the first record and then read through the whole table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. If a table has 1,000 rows, this is at least 100 times faster than reading sequentially. Note that if you need to access almost all 1,000 rows, it is faster to read sequentially, because that minimizes disk seeks.

Most MySQL indexes (PRIMARY KEY, UNIQUE, INDEX, and FULLTEXT) are stored in B-trees. Exceptions are that indexes on spatial column types use R-trees, and MEMORY (HEAP) tables support hash indexes.

Strings are automatically prefix- and end-space compressed. See Section 13.1.4, "CREATE INDEX Syntax".

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in MEMORY tables) are described at the end of this section.

Indexes are used for these operations:

- To quickly find the rows that match a WHERE clause.

- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows.

- To retrieve rows from other tables when performing joins.

- To find the MIN() or MAX() value for a specific indexed column key_col. This is optimized by a preprocessor that checks whether you are using WHERE $key\_part\_\# = constant$ on all key parts that occur before key_col in the index. In this case, MySQL does a single key lookup for each MIN() or MAX() expression and replace it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

  ```
  SELECT MIN(key_part2),MAX(key_part2)
  FROM tbl_name WHERE key_part1=10;
  ```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable key (for example, ORDER BY key_part1, key_part2). If all key parts are followed by DESC, the key is read in reverse order. See Section 7.2.12, "How MySQL Optimizes ORDER BY".

- In some cases, a query can be optimized to retrieve values without consulting the data rows. If a query uses only columns from a table that are numeric and that form a leftmost prefix for some key, the selected values may be retrieved from the index tree for greater speed:

  ```
  SELECT key_part3 FROM tbl_name WHERE key_part1=1
  ```

Suppose that you issue the following SELECT statement:

```
mysql> SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on col1 and col2, the appropriate rows can be fetched directly. If separate single-column indexes exist on col1 and col2, the optimizer tries to find the most restrictive index by deciding which index finds fewer rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to find rows. For example, if you have a three-column index on (col1, col2, col3), you have indexed search capabilities on (col1), (col1, col2), and (col1, col2, col3).

MySQL can't use a partial index if the columns don't form a leftmost prefix of the index. Suppose that you have the SELECT statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on (col1, col2, col3), only the first of the preceding queries uses the index. The second and third queries do involve indexed columns, but (col2) and (col2, col3) are not leftmost prefixes of (col1, col2, col3).

A B-tree index can be used for column comparisons in expressions that use the =, >, >=, <, <=, or BETWEEN operators. The index also can be used for LIKE comparisons if the argument to LIKE is a constant string that doesn't start with a wildcard character. For example, the following SELECT statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%_ck%';
```

In the first statement, only rows with 'Patrick' <= key_col < 'Patricl' are considered. In the second statement, only rows with 'Pat' <= key_col < 'Pau' are considered.

The following SELECT statements do not use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the LIKE value begins with a wildcard character. In the second statement, the LIKE value is not a constant.

MySQL 4.0 and up performs an additional LIKE optimization. If you use ... LIKE '%string%' and string is longer than three characters, MySQL uses the Turbo Boyer-Moore algorithm to initialize the pattern for the string and then use this pattern to perform the search quicker.

Searching using col_name IS NULL uses indexes if col_name is indexed.

Any index that doesn't span all AND levels in the WHERE clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every AND group.

The following WHERE clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3
    /* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2
    /* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5
    /* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These WHERE clauses do *not* use indexes:

```
    /* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2
    /* Index is not used in both AND parts */
... WHERE index=1 OR A=10
    /* No index spans all rows  */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One way this occurs is when the optimizer estimates that using the index would require MySQL to access a large percentage of the rows in the table. (In this case, a table scan is probably much faster, because it requires fewer seeks.) However, if such a query uses LIMIT to only retrieve part of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

Hash indexes have somewhat different characteristics than those just discussed:

- They are used only for equality comparisons that use the = or <=> operators (but are *very* fast). They are not used for comparison operators such as < that find a range of values.

- The optimizer cannot use a hash index to speed up ORDER BY operations. (This type of index cannot be used to search for the next entry in order.)

- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a MyISAM table to a hash-indexed MEMORY table.

- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

7.4.6. The MyISAM Key Cache

To minimize disk I/O, the MyISAM storage engine employs a strategy that is used by many database management systems. It exploits a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the key cache (key buffer) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.

- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system filesystem cache.

This section first describes the basic operation of the MyISAM key cache. Then it discusses changes made in MySQL 4.1 that improve key cache performance and that enable you to better control cache operation:

- Access to the key cache no longer is serialized among threads. Multiple threads can access the cache concurrently.

- You can set up multiple key caches and assign table indexes to specific caches.

The key cache mechanism also is used for `ISAM` tables. However, the significance of this fact is on the wane. `ISAM` table use has been decreasing since MySQL 3.23 when `MyISAM` was introduced. MySQL 4.1 carries this trend further; the `ISAM` storage engine is disabled by default.

You can control the size of the key cache by means of the `key_buffer_size` system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the `key_buffer_size` value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native filesystem buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the `MyISAM` index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are non-leaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered "dirty." In this case, before being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an LRU (Least Recently Used) strategy: When choosing a block for replacement, it selects the least recently used index block. To be able to make such a choice easy, the key cache module maintains a special queue (LRU chain) of all used blocks. When a block is accessed, it is placed at the end of the queue. When blocks need to be replaced, blocks at the beginning of the queue are the least recently used and become the first candidates for eviction.

7.4.6.1. Shared Key Cache Access

Prior to MySQL 4.1, access to the key cache is serialized: No two threads can access key cache buffers simultaneously. The server processes a request for an index block only after it has finished processing the previous request. As a result, a request for an index block not present in any key cache buffer blocks access by other threads while a buffer is being updated to contain the requested index block.

Starting from version 4.1.0, the server supports shared access to the key cache:

- A buffer that is not being updated can be accessed by multiple threads.

- A buffer that is being updated causes threads that need to use it to wait until the update is complete.

- Multiple threads can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache allows the server to improve throughput significantly.

7.4.6.2. Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among

threads entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL 4.1.1 offers the feature of multiple key caches. This allows you to assign different table indexes to different key caches.

When there can be multiple key caches, the server must know which cache to use when processing queries for a given `MyISAM` table. By default, all `MyISAM` table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the `CACHE INDEX` statement.

For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+---------+--------------------+----------+----------+
| Table   | Op                 | Msg_type | Msg_text |
+---------+--------------------+----------+----------+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+---------+--------------------+----------+----------+
```

Note: If the server has been built with the `ISAM` storage engine enabled, `ISAM` tables use the key cache mechanism. However, `ISAM` indexes use only the default key cache and cannot be reassigned to a different cache.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a `SET GLOBAL` parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

Note that you cannot destroy the default key cache. An attempt to do this will be ignored:

```
mysql> set global key_buffer_size = 0;

mysql> show variables like 'key_buffer_size';
+-----------------+---------+
| Variable_name   | Value   |
+-----------------+---------+
| key_buffer_size | 8384512 |
+-----------------+---------+
```

Key cache variables are structured system variables that have a name and components. For `keycache1.key_buffer_size`, `keycache1` is the cache variable name and `key_buffer_size` is the cache component. See Section 9.4.1, "Structured System Variables" for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, we recommend a strategy that uses three key caches:

- A hot key cache that takes up 20% of the space allocated for all key caches. This is used for tables that are heavily used for searches but that are not updated.

- A cold key cache that takes up 20% of the space allocated for all key caches. This is used for medium-sized intensively modified tables, such as temporary tables.

- A warm key cache that takes up 60% of the key cache space. This is the default key cache, to be

used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Queries that access tables assigned to one cache do not compete with queries that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.

- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to non-leaf nodes of the index B-tree remain in the cache.

- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read in from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

`CACHE INDEX` sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init-file` option that names a file containing `CACHE INDEX` statements to be executed. For example:

```
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql
```

The statements in `mysqld_init.sql` are executed each time the server starts. It should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```
CACHE INDEX a.t1, a.t2, b.t3 IN hot_cache
CACHE INDEX a.t4, b.t5, b.t6 IN cold_cache
```

7.4.6.3. Midpoint Insertion Strategy

By default, the key cache management system of MySQL 4.1 uses the LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the "midpoint insertion strategy."

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sub-chain and a warm sub-chain. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not "too short," always containing at least `key_cache_division_limit` percent of the key cache blocks. `key_cache_division_limit` is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sub-chain. After a certain number of hits (accesses of the block), it is promoted to the hot sub-chain. At present, the number of hits required to promote a block (3) is the same for all index blocks. In the future, we will allow the hit count to depend on the B-tree level of the node corresponding to an index block: Fewer hits are required for promotion of an index block if it contains a non-leaf node from the upper levels of the index B-tree than if it contains a leaf node.

A block promoted into the hot sub-chain is placed at the end of the chain. The block then circulates

within this sub-chain. If the block stays at the beginning of the sub-chain for a long enough time, it is demoted to the warm chain. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing *N* blocks, the block at the beginning of the hot sub-chain not accessed within the last *N**`key_cache_age_threshold/100` hits is to be moved to the beginning of the warm sub-chain. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sub-chain.

The midpoint insertion strategy allows you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sub-chain during an index scan operation as well.

7.4.6.4. Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its non-leaf nodes, then it makes sense to preload the key cache with index blocks before starting to use it. Preloading allows you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in a random order, not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
| Table   | Op           | Msg_type | Msg_text |
+---------+--------------+----------+----------+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+---------+--------------+----------+----------+
```

The `IGNORE LEAVES` modifier causes only blocks for the non-leaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the non-leaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

7.4.6.5. Key Cache Block Size

MySQL 4.1 introduces a new `key_cache_block_size` variable on a per-key cache basis. This variable specifies the size of the block buffers for a key cache. It is intended to allow tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

Currently, you cannot control the size of the index blocks in a table. This size is set by the server when the `.MYI` index file is created, depending on the size of the keys in the indexes present in the table definition. In most cases, it is set equal to the I/O buffer size. In the future, this will be changed

and then the `key_cache_block_size` variable is fully employed.

7.4.6.6. Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you set other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native filesystem caching. Filesystem caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. Once the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of filesystem caching for the indexes ceases.

7.4.7. How MySQL Counts Open Tables

When you execute a `mysqladmin status` command, you'll see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have only six tables.

MySQL is multi-threaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client threads having different states on the same table, the table is opened independently by each concurrent thread. This takes some memory but normally increases performance. With `MyISAM` tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all threads.) The `ISAM` storage engine shares this behavior.

You can read more about this topic in the next section. See Section 7.4.8, "How MySQL Opens and Closes Tables".

7.4.8. How MySQL Opens and Closes Tables

The `table_cache`, `max_connections`, and `max_tmp_tables` system variables affect the maximum number of files the server keeps open. If you increase one or more of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems allow you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

`table_cache` is related to `max_connections`. For example, for 200 concurrent running connections, you should have a table cache size of at least $200 * N$, where N is the maximum number of tables in a join. You also need to reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_cache` setting. If `table_cache` is set too high, MySQL may run out of file descriptors and refuse connections, fail to perform queries, and be very unreliable. You also have to take into account that the `MyISAM` storage engine needs two file descriptors for each unique open table. You can increase the number of file descriptors available for MySQL with the `--open-files-limit` startup option to `mysqld_safe`. See Section A.2.17, "File Not Found".

The cache of open tables is kept at a level of `table_cache` entries. The default value is 64; this can be changed with the `--table_cache` option to `mysqld`. Note that MySQL may temporarily open even more tables to be able to execute queries.

An unused table is closed and removed from the table cache under the following circumstances:

• When the cache is full and a thread tries to open a table that is not in the cache.

• When the cache contains more than `table_cache` entries and a thread is no longer using a table.

• When a table flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

• Tables that are not currently in use are released, in least recently used order.

• If a new table needs to be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary.

When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor, for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache isn't full). See Section 13.2.3, "HANDLER Syntax".

You can determine whether your table cache is too small by checking the `mysqld` status variable `Opened_tables`:

```
mysql> SHOW STATUS LIKE 'Opened_tables';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Opened_tables | 2741  |
+---------------+-------+
```

If the value is quite big, even when you haven't issued a lot of `FLUSH TABLES` statements, you should increase your table cache size. See Section 5.3.3, "Server System Variables" and Section 5.3.4, "Server Status Variables".

7.4.9. Drawbacks to Creating Many Tables in the Same Database

If you have many `MyISAM` or `ISAM` tables in a database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by making the table cache larger.

7.5. Optimizing the MySQL Server

7.5.1. System Factors and Startup Parameter Tuning

We start with system-level factors, because some of these decisions must be made very early to achieve large performance gains. In other cases, a quick look at this section may suffice. However, it is always nice to have a sense of how much can be gained by changing things at this level.

The default operating system to use is very important! To get the best use of multiple-CPU machines, you should use Solaris (because its threads implementation works really well) or Linux (because the 2.4 kernel has really good SMP support). Note that older Linux kernels have a 2GB filesize limit by default. If you have such a kernel and a desperate need for files larger than 2GB, you should get the Large File Support (LFS) patch for the ext2 filesystem. Other filesystems such as ReiserFS and XFS do not have this 2GB limitation.

Before using MySQL in production, we advise you to test it on your intended platform.

Other tips:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.

- Use the `--skip-external-locking` MySQL option to avoid external locking. This option is on by default as of MySQL 4.0. Before that, it is on by default when compiling with MIT-pthreads, because `flock()` isn't fully supported by MIT-pthreads on all platforms. It's also on by default for Linux because Linux file locking is not yet safe.

  Note that the `--skip-external-locking` option does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run `myisamchk`. On some systems this option is mandatory, because the external locking does not work in any case.

  The only case when you can't use `--skip-external-locking` is if you run multiple MySQL *servers* (not clients) on the same data, or if you run `myisamchk` to check (not repair) a table without telling the server to flush and lock the tables first.

  You can still use `LOCK TABLES` and `UNLOCK TABLES` even if you are using `--skip-external-locking`.

7.5.2. Tuning Server Parameters

You can determine the default buffer sizes used by the `mysqld` server with this command (prior to MySQL 4.1, omit `--verbose`):

```
shell> mysqld --verbose --help
```

This command produces a list of all `mysqld` options and configurable system variables. The output includes the default variable values and looks something like this:

```
back_log                   current value: 5
bdb_cache_size             current value: 1048540
binlog_cache_size          current value: 32768
connect_timeout            current value: 5
delayed_insert_limit       current value: 100
delayed_insert_timeout     current value: 300
delayed_queue_size         current value: 1000
flush_time                 current value: 0
interactive_timeout        current value: 28800
join_buffer_size           current value: 131072
key_buffer_size            current value: 1048540
```

```
long_query_time            current value: 10
lower_case_table_names     current value: 0
max_allowed_packet         current value: 1048576
max_binlog_cache_size      current value: 4294967295
max_connect_errors         current value: 10
max_connections            current value: 100
max_delayed_threads        current value: 20
max_heap_table_size        current value: 16777216
max_join_size              current value: 4294967295
max_sort_length            current value: 1024
max_tmp_tables             current value: 32
max_write_lock_count       current value: 4294967295
myisam_sort_buffer_size    current value: 8388608
net_buffer_length          current value: 16384
net_read_timeout           current value: 30
net_retry_count            current value: 10
net_write_timeout          current value: 60
read_buffer_size           current value: 131072
read_rnd_buffer_size       current value: 262144
slow_launch_time           current value: 2
sort_buffer                current value: 2097116
table_cache                current value: 64
thread_concurrency         current value: 10
thread_stack               current value: 131072
tmp_table_size             current value: 1048576
wait_timeout               current value: 28800
```

If there is a `mysqld` server currently running, you can see what values it actually is using for the system variables by connecting to it and issuing this statement:

```
mysql> SHOW VARIABLES;
```

You can also see some statistical and status indicators for a running server by issuing this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also can be obtained using `mysqladmin`:

```
shell> mysqladmin variables
shell> mysqladmin extended-status
```

You can find a full description for all system and status variables in Section 5.3.3, "Server System Variables" and Section 5.3.4, "Server Status Variables".

MySQL uses algorithms that are very scalable, so you can usually run with very little memory. However, normally you get better performance by giving MySQL more memory.

When tuning a MySQL server, the two most important variables to configure are `key_buffer_size` and `table_cache`. You should first feel confident that you have these set appropriately before trying to change any other variables.

The following examples indicate some typical variable values for different runtime configurations. The examples use the `mysqld_safe` script and use `--var_name=value` syntax to set the variable `var_name` to the value `value`. This syntax is available as of MySQL 4.0. For older versions of MySQL, take the following differences into account:

- Use `safe_mysqld` rather than `mysqld_safe`.

- Set variables using `--set-variable=var_name=value` or `-O var_name=value` syntax.

- For variable names that end in `_size`, you may need to specify them without `_size`. For ex-

ample, the old name for `sort_buffer_size` is `sort_buffer`. The old name for `read_buffer_size` is `record_buffer`. To see which variables your version of the server recognizes, use `mysqld --help`.

If you have at least 256MB of memory and many tables and want maximum performance with a moderate number of clients, you should use something like this:

```
shell> mysqld_safe --key_buffer_size=64M --table_cache=256 \
         --sort_buffer_size=4M --read_buffer_size=1M &
```

If you have only 128MB of memory and only a few tables, but you still do a lot of sorting, you can use something like this:

```
shell> mysqld_safe --key_buffer_size=16M --sort_buffer_size=1M
```

If there are very many simultaneous connections, swapping problems may occur unless `mysqld` has been configured to use very little memory for each connection. `mysqld` performs better if you have enough memory for all connections.

With little memory and lots of connections, use something like this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=100K \
         --read_buffer_size=100K &
```

Or even this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=16K \
         --table_cache=32 --read_buffer_size=8K \
         --net_buffer_length=1K &
```

If you are doing `GROUP BY` or `ORDER BY` operations on tables that are much larger than your available memory, you should increase the value of `read_rnd_buffer_size` to speed up the reading of rows after sorting operations.

When you have installed MySQL, the `support-files` directory contains some different `my.cnf` sample files: `my-huge.cnf`, `my-large.cnf`, `my-medium.cnf`, and `my-small.cnf`. You can use these as a basis for optimizing your system.

Note that if you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file.

To see the effects of a parameter change, do something like this (prior to MySQL 4.1, omit `--verbose`):

```
shell> mysqld --key_buffer_size=32M --verbose --help
```

The variable values are listed near the end of the output. Make sure that the `--verbose` and `--help` options are last. Otherwise, the effect of any options listed after them on the command line are not reflected in the output.

For information on tuning the `InnoDB` storage engine, see Section 15.12, "`InnoDB` Performance Tuning Tips".

7.5.3. Controlling Query Optimizer Performance

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between "good" and "bad" plans can be orders of magnitude (that is,

seconds versus hours or even days), most query optimizers, including that of MySQL, perform more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7-10) this is not a problem. However, when bigger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server performance.

MySQL 5.0.1 introduces a new more flexible method for query optimization that allows the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled via two system variables:

- The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of "educated guess" rarely misses optimal plans, while it may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed better query plans, then this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Notice that even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.

- The `optimizer_search_depth` variable tells how far in the "future" of each incomplete plan the optimizer should look in order to evaluate whether it should be expanded further. Smaller values of `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For example, queries with 12-13 or more tables may easily require hours and even days to compile if `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` equal to 3 or 4, the compiler may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this variable can be set to 0 to tell the optimizer to determine the value automatically.

7.5.4. How Compiling and Linking Affects the Speed of MySQL

Most of the following tests were performed on Linux with the MySQL benchmarks, but they should give some indication for other operating systems and workloads.

You get the fastest executables when you link with `-static`.

On Linux, you get the fastest code when compiling with `pgcc` and `-O3`. You need about 200MB memory to compile `sql_yacc.cc` with these options, because `gcc`/`pgcc` needs a lot of memory to make all functions inline. You should also set `CXX=gcc` when configuring MySQL to avoid inclusion of the `libstdc++` library, which is not needed. Note that with some versions of `pgcc`, the resulting code runs only on true Pentium processors, even if you use the compiler option indicating that you want the resulting code to work on all x586-type processors (such as AMD).

By just using a better compiler and better compiler options, you can get a 10-30% speed increase in your application. This is particularly important if you compile the MySQL server yourself.

We have tested both the Cygnus CodeFusion and Fujitsu compilers, but when we tested them, neither was sufficiently bug-free to allow MySQL to be compiled with optimizations enabled.

The standard MySQL binary distributions are compiled with support for all character sets. When you compile MySQL yourself, you should include support only for the character sets that you are going to use. This is controlled by the `--with-charset` option to `configure`.

Here is a list of some measurements that we have made:

- If you use `pgcc` and compile everything with `-O6`, the `mysqld` server is 1% faster than with `gcc` 2.95.2.

- If you link dynamically (without `-static`), the result is 13% slower on Linux. Note that you still can use a dynamically linked MySQL library for your client applications. It is the server that is most critical for performance.

- If you strip your `mysqld` binary with `strip mysqld`, the resulting binary can be up to 4% faster.

- For a connection from a client to a server running on the same host, if you connect using TCP/IP rather than a Unix socket file, performance is 7.5% slower. (On Unix, if you connect to the host-name `localhost`, MySQL uses a socket file by default.)

- For TCP/IP connections from a client to a server, connecting to a remote server on another host is 8-11% slower than connecting to the local server on the same host, even for connections over 100Mb/s Ethernet.

- When running our benchmark tests using secure connections (all data encrypted with internal SSL support) performance was 55% slower than for unencrypted connections.

- If you compile with `--with-debug=full`, most queries are 20% slower. Some queries may take substantially longer; for example, the MySQL benchmarks ran 35% slower. If you use `--with-debug` (without `=full`), the slowdown is only 15%. For a version of `mysqld` that has been compiled with `--with-debug=full`, you can disable memory checking at runtime by starting it with the `--skip-safemalloc` option. The execution speed should then be close to that obtained when configuring with `--with-debug`.

- On a Sun UltraSPARC-IIe, a server compiled with Forte 5.0 is 4% faster than one compiled with `gcc` 3.2.

- On a Sun UltraSPARC-IIe, a server compiled with Forte 5.0 is 4% faster in 32-bit mode than in 64-bit mode.

- Compiling with `gcc` 2.95.2 for UltraSPARC with the `-mcpu=v8 -Wa,-xarch=v8plusa` options gives 4% more performance.

- On Solaris 2.5.1, MIT-pthreads is 8-12% slower than Solaris native threads on a single processor. With more load or CPUs, the difference should be larger.

- Compiling on Linux-x86 using `gcc` without frame pointers (`-fomit-frame-pointer` or `-fomit-frame-pointer -ffixed-ebp`) makes `mysqld` 1-4% faster.

Binary MySQL distributions for Linux that are provided by MySQL AB used to be compiled with `pgcc`. We had to go back to regular `gcc` due to a bug in `pgcc` that would generate code that does not run on AMD. We will continue using `gcc` until that bug is resolved. In the meantime, if you have a non-AMD machine, you can get a faster binary by compiling with `pgcc`. The standard MySQL Linux binary is linked statically to make it faster and more portable.

7.5.5. How MySQL Uses Memory

The following list indicates some of the ways that the `mysqld` server uses memory. Where applicable, the name of the system variable relevant to the memory use is given:

- The key buffer (variable `key_buffer_size`) is shared by all threads; other buffers used by the server are allocated as needed. See Section 7.5.2, "Tuning Server Parameters".

- Each connection uses some thread-specific space:

- A stack (default 64KB, variable `thread_stack`)

- A connection buffer (variable `net_buffer_length`)

- A result buffer (variable `net_buffer_length`)

  The connection buffer and result buffer are dynamically enlarged up to `max_allowed_packet` when needed. While a query is running, a copy of the current query string is also allocated.

- All threads share the same base memory.

- Only compressed `ISAM` and `MyISAM` tables are memory mapped. This is because the 32-bit memory space of 4GB is not large enough for most big tables. When systems with a 64-bit address space become more common, we may add general support for memory mapping.

- Each request that performs a sequential scan of a table allocates a read buffer (variable `read_buffer_size`).

- When reading rows in "random" order (for example, after a sort), a random-read buffer may be allocated to avoid disk seeks. (variable `read_rnd_buffer_size`).

- All joins are done in one pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based (`HEAP`) tables. Temporary tables with a large record length (calculated as the sum of all column lengths) or that contain `BLOB` columns are stored on disk.

  One problem before MySQL 3.23.2 is that if an internal in-memory heap table exceeds the size of `tmp_table_size`, the error `The table `*tbl_name*` is full` occurs. From 3.23.2 on, this is handled automatically by changing the in-memory heap table to a disk-based `MyISAM` table as necessary. To work around this problem for older servers, you can increase the temporary table size by setting the `tmp_table_size` option to `mysqld`, or by setting the SQL option `SQL_BIG_TABLES` in the client program. See Section 13.5.3, "`SET` Syntax".

  In MySQL 3.20, the maximum size of the temporary table is `record_buffer*16`; if you are using this version, you have to increase the value of `record_buffer`. You can also start `mysqld` with the `--big-tables` option to always store temporary tables on disk. However, this affects the speed of many complicated queries.

- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See Section A.4.4, "Where MySQL Stores Temporary Files".

- Almost all parsing and calculating is done in a local memory store. No memory overhead is needed for small items, so the normal slow memory allocation and freeing is avoided. Memory is allocated only for unexpectedly large strings; this is done with `malloc()` and `free()`.

- For each `MyISAM` and `ISAM` table that is opened, the index file is opened once and the data file is opened once for each concurrently running thread. For each concurrent thread, a table structure, column structures for each column, and a buffer of size $3 * N$ are allocated (where N is the maximum row length, not counting `BLOB` columns). A `BLOB` column requires five to eight bytes plus the length of the `BLOB` data. The `MyISAM` and `ISAM` storage engines maintain one extra row buffer for internal use.

- For each table having `BLOB` columns, a buffer is enlarged dynamically to read in larger `BLOB` values. If you scan a table, a buffer as large as the largest `BLOB` value is allocated.

- Handler structures for all in-use tables are saved in a cache and managed as a FIFO. By default, the cache has 64 entries. If a table has been used by two running threads at the same time, the cache contains two entries for the table. See Section 7.4.8, "How MySQL Opens and Closes Tables".

- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables

that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. You can verify this by checking available swap with `swap -s`. We have tested `mysqld` with several memory-leakage detectors (both commercial and open source), so there should be no memory leaks.

7.5.6. How MySQL Uses DNS

When a new client connects to `mysqld`, `mysqld` spawns a new thread to handle the request. This thread first checks whether the hostname is in the hostname cache. If not, the thread attempts to resolve the hostname:

• If the operating system supports the thread-safe `gethostbyaddr_r()` and `gethostbyname_r()` calls, the thread uses them to perform hostname resolution.

• If the operating system doesn't support the thread-safe calls, the thread locks a mutex and calls `gethostbyaddr()` and `gethostbyname()` instead. In this case, no other thread can resolve hostnames that are not in the hostname cache until the first thread unlocks the mutex.

You can disable DNS hostname lookups by starting `mysqld` with the `--skip-name-resolve` option. However, in this case, you can use only IP numbers in the MySQL grant tables.

If you have a very slow DNS and many hosts, you can get more performance by either disabling DNS lookups with `--skip-name-resolve` or by increasing the `HOST_CACHE_SIZE` define (default value: 128) and recompiling `mysqld`.

You can disable the hostname cache by starting the server with the `--skip-host-cache` option. To clear the hostname cache, issue a `FLUSH HOSTS` statement or execute the `mysqladmin flush-hosts` command.

If you want to disallow TCP/IP connections entirely, start `mysqld` with the `--skip-networking` option.

7.6. Disk Issues

• Disk seeks are a big performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.

• Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:

 • Using symbolic links

 This means that, for `MyISAM` tables, you symlink the index file and/or data file from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See Section 7.6.1, "Using Symbolic Links".

 •
 Striping

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the Nth block on the (N mod number_of_disks) disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See Section 7.1.5, "Using Your Own Benchmarks".

The speed difference for striping is *very* dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

- For reliability you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need 2*N drives to hold N drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.

- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID N disk. RAID N can be a problem if you have many writes, due to the time required to update the parity bits.

- On Linux, you can get much more performance by using `hdparm` to configure your disk's interface. (Up to 100% under load is not uncommon.) The following `hdparm` options should be quite good for MySQL, and probably for many other applications:

```
hdparm -m 16 -d 1
```

Note that performance and reliability when using this command depends on your hardware, so we strongly suggest that you test your system thoroughly after using `hdparm`. Please consult the `hdparm` manual page for more information. If `hdparm` is not used wisely, filesystem corruption may result, so back up everything before experimenting!

- You can also set the parameters for the filesystem that the database uses:

If you don't need to know when files were last accessed (which is not really useful on a database server), you can mount your filesystems with the `-o noatime` option. That skips updates to the last access time in inodes on the filesystem, which avoids some disk seeks.

On many operating systems, you can set a filesystem to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you more performance without sacrificing too much reliability. (This flag is on by default on Linux.)

7.6.1. Using Symbolic Links

You can move tables and databases from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disk.

The recommended way to do this is to just symlink databases to a different disk. Symlink tables only as a last resort.

7.6.1.1. Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is to first create a directory on some disk where you have free space and then create a symlink to it from the MySQL data directory.

```
shell> mkdir /dr1/databases/test
shell> ln -s /dr1/databases/test /path/to/datadir
```

MySQL doesn't support linking one directory to multiple databases. Replacing a database directory with a symbolic link works fine as long as you don't make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```
shell> cd /path/to/datadir
shell> ln -s db1 db2
```

For any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, there are problems.

If you really need to do this, you can change one of the source files. The file to modify depends on your version of MySQL. For MySQL 4.0 and up, look for the following statement in the `mysys/my_symlink.c` file:

```
if (!(MyFlags & MY_RESOLVE_LINK) ||
    (!lstat(filename,&stat_buff) && S_ISLNK(stat_buff.st_mode)))
```

Before MySQL 4.0, look for this statement in the `mysys/mf_format.c` file:

```
if (flag & 32 || (!lstat(to,&stat_buff) && S_ISLNK(stat_buff.st_mode)))
```

Change the statement to this:

```
if (1)
```

On Windows, you can use internal symbolic links to directories by compiling MySQL with `-DUSE_SYMDIR`. This allows you to put different databases on different disks. See Section 7.6.1.3, "Using Symbolic Links for Databases on Windows". (It is necessary to define `USE_SYMDIR` explicitly only before MySQL 4.0. As of MySQL 4.0, symbolic link support is enabled by default for all Windows servers.)

7.6.1.2. Using Symbolic Links for Tables on Unix

Before MySQL 4.0, you should not symlink tables unless you are *very* careful with them. The problem is that if you run `ALTER TABLE`, `REPAIR TABLE`, or `OPTIMIZE TABLE` on a symlinked table, the symlinks are removed and replaced by the original files. This happens because these statements work by creating a temporary file in the database directory and replacing the original file with the temporary file when the statement operation is complete.

You should not symlink tables on systems that don't have a fully working `realpath()` call. (At least Linux and Solaris support `realpath()`). You can check whether your system supports symbolic links by issuing a `SHOW VARIABLES LIKE 'have_symlink'` statement.

In MySQL 4.0, symlinks are fully supported only for `MyISAM` tables. For other table types, you may get strange problems if you try to use symbolic links on files in the operating system with any of the preceding statements.

The handling of symbolic links for `MyISAM` tables in MySQL 4.0 works the following way:

• In the data directory, you always have the table definition file, the data file, and the index file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The definition file cannot.

• You can symlink the data file and the index file independently to different directories.

• The symlinking can be done manually from the command line with `ln -s` if `mysqld` is not running. With SQL, you can instruct the server to perform the symlinking by using the DATA

DIRECTORY and INDEX DIRECTORY options to CREATE TABLE. See Section 13.1.5, "CREATE TABLE Syntax".

- myisamchk does not replace a symlink with the data file or index file. It works directly on the file a symlink points to. Any temporary files are created in the directory where the data file or index file is located.

- When you drop a table that is using symlinks, both the symlink and the file the symlink points to are dropped. This is a good reason why you should *not* run mysqld as root or allow users to have write access to the MySQL database directories.

- If you rename a table with ALTER TABLE ... RENAME and you don't move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you use ALTER TABLE ... RENAME to move a table to another database, the table is moved to the other database directory. The old symlinks and the files to which they pointed are deleted. In other words, the new table is not symlinked.

- If you are not using symlinks, you should use the --skip-symbolic-links option to mysqld to ensure that no one can use mysqld to drop or rename a file outside of the data directory.

SHOW CREATE TABLE doesn't report if a table has symbolic links prior to MySQL 4.0.15. This is also true for mysqldump, which uses SHOW CREATE TABLE to generate CREATE TABLE statements.

Table symlink operations that are not yet supported:

- ALTER TABLE ignores the DATA DIRECTORY and INDEX DIRECTORY table options.

- BACKUP TABLE and RESTORE TABLE don't respect symbolic links.

- The .frm file must *never* be a symbolic link (as indicated previously, only the data and index files can be symbolic links). Attempting to do this (for example, to make synonyms) produces incorrect results. Suppose that you have a database db1 under the MySQL data directory, a table tbl1 in this database, and in the db1 directory you make a symlink tbl2 that points to tbl1:

```
shell> cd /path/to/datadir/db1
shell> ln -s tbl1.frm tbl2.frm
shell> ln -s tbl1.MYD tbl2.MYD
shell> ln -s tbl1.MYI tbl2.MYI
```

There are problems if one thread reads db1.tbl1 and another thread updates db1.tbl2:

- The query cache is fooled (it believes tbl1 has not been updated so it returns outdated results).

- ALTER statements on tbl2 also fail.

7.6.1.3. Using Symbolic Links for Databases on Windows

Beginning with MySQL 3.23.16, the mysqld-max and mysql-max-nt servers for Windows are compiled with the -DUSE_SYMDIR option. This allows you to put a database directory on a different disk by setting up a symbolic link to it. This is similar to the way that symbolic links work on Unix, although the procedure for setting up the link is different.

As of MySQL 4.0, symbolic links are enabled by default. If you don't need them, you can disable them with the skip-symbolic-links option:

```
[mysqld]
skip-symbolic-links
```

Before MySQL 4.0, symbolic links are disabled by default. To enable them, you should put the following entry in your `my.cnf` or `my.ini` file:

```
[mysqld]
symbolic-links
```

On Windows, you make a symbolic link to a MySQL database by creating a file in the data directory that contains the path to the destination directory. The file should be named `db_name.sym`, where *db_name* is the database name.

Suppose that the MySQL data directory is `C:\mysql\data` and you want to have database `foo` located at `D:\data\foo`. Set up a symlink like this:

1. Make sure that the `D:\data\foo` directory exists by creating it if necessary. If you have a database directory named `foo` in the data directory, you should move it to `D:\data`. Otherwise, the symbolic link is ineffective. To avoid problems, the server should not be running when you move the database directory.

2. Create a file `C:\mysql\data\foo.sym` that contains the pathname `D:\data\foo\`.

After that, all tables created in the database `foo` are created in `D:\data\foo`. Note that the symbolic link is not used if a directory with the database name exists in the MySQL data directory.

Chapter 8. MySQL Client and Utility Programs

There are many different MySQL client programs that connect to the server to access databases or perform administrative tasks. Other utilities are available as well. These do not communicate with the server but perform MySQL-related operations.

This chapter provides a brief overview of these programs and then a more detailed description of each one. The descriptions indicate how to invoke the programs and the options they understand. See Chapter 4, *Using MySQL Programs* for general information on invoking programs and specifying program options.

8.1. Overview of the Client-Side Scripts and Utilities

The following list briefly describes the MySQL client programs and utilities:

* `myisampack`

  A utility that compresses `MyISAM` tables to produce smaller read-only tables. See Section 8.2, "myisampack — Generate Compressed, Read-Only MyISAM Tables".

* `mysql`

  The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See Section 8.3, "mysql — The MySQL Command-Line Tool".

* `mysqlaccess`

  A script that checks the access privileges for a host, user, and database combination.

* `mysqladmin`

  A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See Section 8.4, "mysqladmin — Client for Administering a MySQL Server".

* `mysqlbinlog`

  A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See Section 8.5, "mysqlbinlog — Utility for Processing Binary Log Files".

* `mysqlcc`

  A client that provides a graphical interface for interacting with the server. See Section 8.6, "mysqlcc, the MySQL Control Center".

* `mysqlcheck`

A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See Section 8.7, "mysqlcheck — A Table Maintenance and Repair Program".

- mysqldump

  A client that dumps a MySQL database into a file as SQL statements or as tab-separated text files. Enhanced freeware originally by Igor Romanenko. See Section 8.8, "mysqldump — A Database Backup Program".

- mysqlhotcopy

  A utility that quickly makes backups of MyISAM or ISAM tables while the server is running. See Section 8.9, "mysqlhotcopy — A Database Backup Program".

- mysqlimport

  A client that imports text files into their respective tables using LOAD DATA INFILE. See Section 8.10, "mysqlimport — A Data Import Program".

- mysqlshow

  A client that displays information about databases, tables, columns, and indexes. See Section 8.11, "mysqlshow — Display Database, Table, and Column Information".

- perror

  A utility that displays the meaning of system or MySQL error codes. See Section 8.12, "perror — Explain Error Codes".

- replace

  A utility program that changes strings in place in files or on the standard input. See Section 8.13, "replace — A String-Replacement Utility".

Each MySQL program takes many different options. However, every MySQL program provides a --help option that you can use to get a full description of the program's different options. For example, try mysql --help.

MySQL clients that communicate with the server using the mysqlclient library use the following environment variables:

MYSQL_UNIX_PORT	The default Unix socket file; used for connections to localhost
MYSQL_TCP_PORT	The default port number; used for TCP/IP connections
MYSQL_PWD	The default password
MYSQL_DEBUG	Debug trace options when debugging
TMPDIR	The directory where temporary tables and files are created

Use of MYSQL_PWD is insecure. See Section 5.7.6, "Keeping Your Password Secure".

You can override the default option values or values specified in environment variables for all standard programs by specifying options in an option file or on the command line. Section 4.3, "Specifying Program Options".

8.2. myisampack — Generate Compressed, Read-Only MyISAM Tables

The myisampack utility compresses MyISAM tables. myisampack works by compressing each column in the table separately. Usually, myisampack packs the data file 40%-70%.

When the table is used later, the information needed to decompress columns is read into memory. This results in much better performance when accessing individual records, because you only have to uncompress exactly one record, not a much larger disk block as when using Stacker on MS-DOS.

MySQL uses mmap() when possible to perform memory mapping on compressed tables. If mmap() doesn't work, MySQL falls back to normal read/write file operations.

A similar utility, pack_isam, compresses ISAM tables. Because ISAM tables are deprecated, this section discusses only myisampack, but the general procedures for using myisampack are also true for pack_isam unless otherwise specified.

Please note the following:

- If the mysqld server was invoked with the --skip-external-locking option, it is not a good idea to invoke myisampack if the table might be updated by the server during the packing process.

- After packing a table, it becomes read-only. This is generally intended (such as when accessing packed tables on a CD). Allowing writes to a packed table is on our TODO list, but with low priority.

- myisampack can pack BLOB or TEXT columns. The older pack_isam program for ISAM tables cannot.

Invoke myisampack like this:

```
shell> myisampack [options] filename ...
```

Each filename should be the name of an index (.MYI) file. If you are not in the database directory, you should specify the pathname to the file. It is permissible to omit the .MYI extension.

myisampack supports the following options:

- --help, -?

  Display a help message and exit.

- --backup, -b

  Make a backup of the table data file using the name tbl_name.OLD.

- --debug[=debug_options], -# [debug_options]

  Write a debugging log. The debug_options string often is 'd:t:o,file_name'.

- --force, -f

  Produce a packed table even if it becomes larger than the original or if the temporary file from an earlier invocation of myisampack exists. (myisampack creates a temporary file named tbl_name.TMD while it compresses the table. If you kill myisampack, the .TMD file might not be deleted.) Normally, myisampack exits with an error if it finds that tbl_name.TMD exists. With --force, myisampack packs the table anyway.

- `--join=big_tbl_name`, `-j big_tbl_name`

  Join all tables named on the command line into a single table `big_tbl_name`. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

- `--packlength=len`, `-p len`

  Specify the record length storage size, in bytes. The value should be 1, 2, or 3. `myisampack` stores all rows with length pointers of 1, 2, or 3 bytes. In most normal cases, `myisampack` can determine the right length value before it begins packing the file, but it may notice during the packing process that it could have used a shorter length. In this case, `myisampack` prints a note that the next time you pack the same file, you could use a shorter record length.

- `--silent`, `-s`

  Silent mode. Write output only when errors occur.

- `--test`, `-t`

  Don't actually pack the table, just test packing it.

- `--tmpdir=path`, `-T path`

  Use the named directory as the location in which to write the temporary table.

- `--verbose`, `-v`

  Verbose mode. Write information about the progress of the packing operation and its result.

- `--version`, `-V`

  Display version information and exit.

- `--wait`, `-w`

  Wait and retry if the table is in use. If the `mysqld` server was invoked with the `--skip-external-locking` option, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
-rw-rw-r--   1 monty    my          994128 Apr 17 19:00 station.MYD
-rw-rw-r--   1 monty    my           53248 Apr 17 19:00 station.MYI
-rw-rw-r--   1 monty    my            5767 Apr 17 19:00 station.frm

28    369   4      no zeros, zerofill(1)               2    9
29    373   4      table-lookup                       11    0
30    377   1                                          3    9
31    378   2      no zeros, zerofill(1)               2    9
32    380   8      no zeros                            2    9
33    388   4      always zero                         2    9
34    392   4      table-lookup                       12    0
35    396   4      no zeros, zerofill(1)              13    9
36    400   4      no zeros, zerofill(1)               2    9
37    404   1                                          2    9
38    405   4      no zeros                            2    9
39    409   4      always zero                         2    9
40    413   4      no zeros                            2    9
41    417   4      always zero                         2    9
42    421   4      no zeros                            2    9
43    425   4      always zero                         2    9
44    429   20     no empty                            3    9
45    449   30     no empty                            3    9
46    479   1                                         14    4
```

```
47      480     1                                                       14      4
48      481     79      no endspace, no empty                           15      9
49      560     79      no empty                                        2       9
50      639     79      no empty                                        2       9
51      718     79      no endspace                                     16      9
52      797     8       no empty                                        2       9
53      805     1                                                       17      1
54      806     1                                                       3       9
55      807     20      no empty                                        3       9
56      827     4       no zeros, zerofill(2)                           2       9
57      831     4       no zeros, zerofill(1)                           2       9
```

myisampack displays the following kinds of information:

- normal

  The number of columns for which no extra packing is used.

- empty-space

  The number of columns containing values that are only spaces; these occupy one bit.

- empty-zero

  The number of columns containing values that are only binary zeros; these occupy one bit.

- empty-fill

  The number of integer columns that don't occupy the full byte range of their type; these are changed to a smaller type. For example, a BIGINT column (eight bytes) can be stored as a TINYINT column (one byte) if all its values are in the range from -128 to 127.

- pre-space

  The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- end-space

  The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- table-lookup

  The column had only a small number of different values, which were converted to an ENUM before Huffman compression.

- zero

  The number of columns for which all values are zero.

- Original trees

  The initial number of Huffman trees.

- After join

  The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, myisamchk -dvv prints additional information about each column:

- Type

  The column type. The value may contain any of the following descriptors:

  - constant

    All rows have the same value.

  - no endspace

    Don't store endspace.

  - no endspace, not_always

    Don't store endspace and don't do endspace compression for all values.

  - no endspace, no empty

    Don't store endspace. Don't store empty values.

  - table-lookup

    The column was converted to an ENUM.

  - zerofill(*n*)

    The most significant *n* bytes in the value are always 0 and are not stored.

  - no zeros

    Don't store zeros.

  - always zero

    Zero values are stored using one bit.

- Huff tree

  The number of the Huffman tree associated with the column.

- Bits

  The number of bits used in the Huffman tree.

After you run myisampack, you must run myisamchk to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

A similar procedure applies for ISAM tables. After using pack_isam, use isamchk to re-create the indexes:

```
shell> isamchk -rq --sort-index --analyze tbl_name.ISM
```

After you have installed the packed table into the MySQL database directory, you should execute mysqladmin flush-tables to force mysqld to start using the new table.

To unpack a packed table, use the --unpack option to myisamchk or isamchk.

8.3. mysql — The MySQL Command-Line

Tool

`mysql` is a simple SQL shell (with GNU `readline` capabilities). It supports interactive and non-interactive use. When used interactively, query results are presented in an ASCII-table format. When used non-interactively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command-line options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by using `mysql_use_result()` rather than `mysql_store_result()` to retrieve the result set.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with '`;`', `\g`, or `\G` and press Enter.

You can run a script simply like this:

```
shell> mysql db_name < script.sql > output.tab
```

8.3.1. Options

`mysql` supports the following options:

*
  `--help, -?`

  Display a help message and exit.

*
  `--batch, -B`

  Print results using tab as the column separator, with each row on a new line. With this option, `mysql` doesn't use the history file.

*
  `--character-sets-dir=path`

  The directory where character sets are installed. See Section 5.9.1, "The Character Set Used for Data and Sorting".

*
  `--compress, -C`

  Compress all information sent between the client and the server if both support compression.

*
  `--database=db_name, -D db_name`

  The database to use. This is useful mainly in an option file.

*
  `--debug[=debug_options], -# [debug_options]`

Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysql.trace'`.

- `--debug-info, -T`

  Print some debugging information when the program exits.

- `--default-character-set=charset`

  Use `charset` as the default character set. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--execute=statement, -e statement`

  Execute the statement and quit. The default output format is like that produced with `--batch`.

- `--force, -f`

  Continue even if an SQL error occurs.

- `--host=host_name, -h host_name`

  Connect to the MySQL server on the given host.

- `--html, -H`

  Produce HTML output.

- `--ignore-space, -i`

  Ignore spaces after function names. The effect of this is described in the discussion for `IGNORE_SPACE` in Section 5.3.2, "The Server SQL Mode".

- `--local-infile[={0|1}]`

  Enable or disable `LOCAL` capability for `LOAD DATA INFILE`. With no value, the option enables `LOCAL`. It may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable `LOCAL`. Enabling `LOCAL` has no effect if the server does not also support it.

- `--named-commands, -G`

  Named commands are *enabled*. Long format commands are allowed as well as shortened `\*` commands. For example, `quit` and `\q` both are recognized.

- `--no-auto-rehash, -A`

  No automatic rehashing. This option causes `mysql` to start faster, but you must issue the `rehash` command if you want to use table and column name completion.

- `--no-beep, -b`

  Do not beep when errors occur.

- `--no-named-commands, -g`

  Named commands are disabled. Use the `\*` form only, or use named commands only at the beginning of a line ending with a semicolon ('`;`'). As of MySQL 3.23.22, `mysql` starts with this option *enabled* by default! However, even with this option, long-format commands still work from the first line.

- `--no-pager`

  Do not use a pager for displaying query output. Output paging is discussed further in Section 8.3.2, "`mysql` Commands".

- `--no-tee`

  Do not copy output to a file. Tee files are discussed further in Section 8.3.2, "`mysql` Commands".

- `--one-database, -O`

  Ignore statements except those for the default database named on the command line. This is useful for skipping updates to other databases in the binary log.

- `--pager[=command]`

  Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat [> filename]`, and so forth. This option works only on Unix. It does not work in batch mode. Output paging is discussed further in Section 8.3.2, "`mysql` Commands".

- `--password[=password], -p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, you are prompted for one. The password should be omitted on SysV-based UNIX systems, as the password may be displayed in the output of `ps`.

- `--port=port_num, -P port_num`

  The TCP/IP port number to use for the connection.

- `--prompt=format_str`

  Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in Section 8.3.2, "`mysql` Commands".

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

  The connection protocol to use. New in MySQL 4.1.

- `--quick, -q`

  Don't cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` doesn't use the history file.

- `--raw, -r`

  Write column values without escape conversion. Often used with the `--batch` option.

- `--reconnect`

  If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect`. New in MySQL 4.1.0.

- `--safe-updates, --i-am-a-dummy, -U`

  Allow only UPDATE and DELETE statements that specify rows to affect using key values. If you have this option in an option file, you can override it by using `--safe-updates` on the command line. See Section 8.3.4, "mysql Tips" for more information about this option.

- `--secure-auth`

  Do not send passwords to the server in old (pre-4.1.1) format. This prevents connections except for servers that use the newer password format. This option was added in MySQL 4.1.1.

- `--show-warnings`

  Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode. This option was added in MySQL 5.0.6.

- `--sigint-ignore`

  Ignore SIGINT signals (typically the result of typing Control-C). This option was added in MySQL 4.1.6.

- `--silent, -s`

  Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

- `--skip-column-names, -N`

  Don't write column names in results.

- `--skip-line-numbers, -L`

  Don't write line numbers for errors. Useful when you want to compare result files that include error messages.

- `--socket=path, -S path`

  The socket file to use for the connection.

- `--table, -t`

  Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- ```
  --tee=file_name
  ```

  Append a copy of output to the given file. This option does not work in batch mode. Tee files are discussed further in Section 8.3.2, "mysql Commands".

- ```
  --unbuffered, -n
  ```

  Flush the buffer after each query.

- ```
  --user=user_name, -u user_name
  ```

  The MySQL username to use when connecting to the server.

- ```
  --verbose, -v
  ```

  Verbose mode. Produce more output. This option can be given multiple times to produce more and more output. (For example, -v -v -v produces the table output format even in batch mode.)

- ```
  --version, -V
  ```

  Display version information and exit.

- ```
  --vertical, -E
  ```

  Print the rows of query output vertically. Without this option, you can specify vertical output for individual statements by terminating them with \G.

- ```
  --wait, -w
  ```

  If the connection cannot be established, wait and retry instead of aborting.

- ```
  --xml, -X
  ```

  Produce XML output.

You can also set the following variables by using --var_name=value options:

- ```
  connect_timeout
  ```

  The number of seconds before connection timeout. (Default value is 0.)

- ```
  max_allowed_packet
  ```

  The maximum packet length to send to or receive from the server. (Default value is 16MB.)

- ```
  max_join_size
  ```

  The automatic limit for rows in a join when using --safe-updates. (Default value is 1,000,000.)

-

```
net_buffer_length
```

The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

•
```
select_limit
```

The automatic limit for SELECT statements when using --safe-updates. (Default value is 1,000.)

It is also possible to set variables by using --set-variable=*var_name=value* or -O *var_name=value* syntax. However, this syntax is deprecated as of MySQL 4.0.

On Unix, the mysql client writes a record of executed statements to a history file. By default, the history file is named .mysql_history and is created in your home directory. To specify a different file, set the value of the MYSQL_HISTFILE environment variable.

If you do not want to maintain a history file, first remove .mysql_history if it exists, and then use either of the following techniques:

• Set the MYSQL_HISTFILE variable to /dev/null. To cause this setting to take effect each time you log in, put the setting in one of your shell's startup files.

• Create .mysql_history as a symbolic link to /dev/null:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

You need do this only once.

8.3.2. `mysql` Commands

mysql sends SQL statements that you issue to the server to be executed. There is also a set of commands that mysql itself interprets. For a list of these commands, type help or \h at the mysql> prompt:

```
mysql> help

MySQL commands:
?          (\h)    Synonym for `help'.
clear      (\c)    Clear command.
connect    (\r)    Reconnect to the server.
                   Optional arguments are db and host.
delimiter  (\d)    Set query delimiter.
edit       (\e)    Edit command with $EDITOR.
ego        (\G)    Send command to mysql server,
                   display result vertically.
exit       (\q)    Exit mysql. Same as quit.
go         (\g)    Send command to mysql server.
help       (\h)    Display this help.
nopager    (\n)    Disable pager, print to stdout.
notee      (\t)    Don't write into outfile.
pager      (\P)    Set PAGER [to_pager].
                   Print the query results via PAGER.
print      (\p)    Print current command.
prompt     (\R)    Change your mysql prompt.
quit       (\q)    Quit mysql.
rehash     (\#)    Rebuild completion hash.
source     (\.)    Execute an SQL script file.
                   Takes a file name as an argument.
status     (\s)    Get status information from the server.
system     (\!)    Execute a system shell command.
```

```
tee        (\T)    Set outfile [to_outfile].
                   Append everything into given outfile.
use        (\u)    Use another database.
                   Takes database name as argument.
warnings   (\W)    Show warnings after every statement.
nowarning  (\w)    Don't show warnings after every statement.
```

Each command has both a long and short form. The long form is not case sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

In the `delimiter` command, you should avoid the use of the backslash ('`\`') character because that is the escape character for MySQL.

The `edit`, `nopager`, `pager`, and `system` commands work only in Unix.

The `status` command provides some information about the connection and the server you are using. If you are running in `--safe-updates` mode, `status` also prints the values for the `mysql` variables that affect your queries.

To log queries and their output, use the `tee` command. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. You can enable this feature on the command line with the `--tee` option, or interactively with the `tee` command. The `tee` file can be disabled interactively with the `notee` command. Executing `tee` again re-enables logging. Without a parameter, the previous file is used. Note that `tee` flushes query results to the file after each statement, just before `mysql` prints its next prompt.

Browsing or searching query results in interactive mode by using Unix programs such as `less`, `more`, or any other similar program is possible with the `--pager` option. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Output paging can be enabled interactively with the `pager` command and disabled with `no-pager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

Output paging works only in Unix because it uses the `popen()` function, which doesn't exist on Windows. For Windows, the `tee` option can be used instead to save query output, although this is not as convenient as `pager` for browsing output in some situations.

A few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

  ```
  mysql> pager cat > /tmp/log.txt
  ```

  You can also pass any options for the program that you want to use as your pager:

  ```
  mysql> pager less -n -i -S
  ```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

  ```
  shell> man less
  ```

- You can specify very complex pager commands for handling query output:

  ```
  mysql> pager cat | tee /dr1/tmp/res.txt \
             | tee /dr2/tmp/res2.txt | less -n -i -S
  ```

In this example, the command would send query results to two files in two different directories on two different filesystems mounted on `/dr1` and `/dr2`, yet still display the results onscreen via `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you don't have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` doesn't log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

From MySQL 4.0.2 on, the default `mysql>` prompt can be reconfigured. The string for defining the prompt can contain the following special sequences:

Option	Description
\v	The server version
\d	The current database
\h	The server host
\p	The current TCP/IP port or socket file
\u	Your username
\U	Your full *user_name@host_name* account name
\\	A literal '\' backslash character
\n	A newline character
\t	A tab character
\	A space (a space follows the backslash)
_	A space
\R	The current time, in 24-hour military time (0-23)
\r	The current time, standard 12-hour time (1-12)
\m	Minutes of the current time
\y	The current year, two digits
\Y	The current year, four digits
\D	The full current date
\s	Seconds of the current time
\w	The current day of the week in three-letter format (Mon, Tue, ...)
\P	am/pm
\o	The current month in numeric format
\O	The current month in three-letter format (Jan, Feb, ...)
\c	A counter that increments for each statement you issue
\S	Semicolon
\'	Single quote
\"	Double quote

'\' followed by any other letter just becomes that letter.

If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

You can set the prompt in several ways:

- Use an environment variable

  You can set the MYSQL_PS1 environment variable to a prompt string. For example:

  ```
  shell> export MYSQL_PS1="(\u@\h) [\d]> "
  ```

- Use an option file

  You can set the prompt option in the [mysql] group of any MySQL option file, such as /etc/my.cnf or the .my.cnf file in your home directory. For example:

  ```
  [mysql]
  prompt=(\\u@\\h) [\\d]>\\_
  ```

  In this example, note that the backslashes are doubled. If you set the prompt using the prompt option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of allowable prompt options and the set of special escape sequences that are recognized in option files. (These sequences are listed in Section 4.3.2, "Using Option Files".) The overlap may cause you problems if you use single backslashes. For example, \s is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in HH:MM:SS> format:

  ```
  [mysql]
  prompt="\\r:\\m:\\s> "
  ```

- Use a command-line option

  You can set the --prompt option on the command line to mysql. For example:

  ```
  shell> mysql --prompt="(\u@\h) [\d]> "
  (user@host) [database]>
  ```

- Interactively

  You can change your prompt interactively by using the prompt (or \R) command. For example:

  ```
  mysql> prompt (\u@\h) [\d]>\_
  PROMPT set to '(\u@\h) [\d]>\_'
  (user@host) [database]>
  (user@host) [database]> prompt
  Returning to default PROMPT of mysql>
  mysql>
  ```

8.3.3. Executing SQL Statements from a Text File

The mysql client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it's also possible to put your SQL statements in a file and then tell mysql to read its input from that file. To do so, create a text file text_file that contains the statements you wish to execute. Then invoke mysql as shown here:

```
shell> mysql db_name < text_file
```

You can also start your text file with a USE `db_name` statement. In this case, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are running mysql, you can execute an SQL script file using the source or \. command:

```
mysql> source filename
mysql> \. filename
```

Sometimes you may want your script to display progress information to the user; for this you can insert some lines like

```
SELECT '<info_to_display>' AS ' ';
```

which outputs <info_to_display>.

For more information about batch mode, see Section 3.5, "Using mysql in Batch Mode".

8.3.4. `mysql` Tips

This section describes some techniques that can help you use mysql more effectively.

8.3.4.1. Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with \G instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
*************************** 1. row ***************************
  msg_nro: 3068
     date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
    reply: monty@no.spam.com
  mail_to: "Thimble Smith" <tim@no.spam.com>
      sbj: UTF-8

Thimble> TODO list and see what happens.

Yes, please do that.

Regards,
Monty

8.3.4.2. Using the `--safe-updates` Option

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). This option was introduced in MySQL 3.23.11. It is helpful for cases when you might have issued a DELETE FROM `tbl_name` statement but forgotten the WHERE clause. Nor-

mally, such a statement deletes all rows from the table. With `--safe-updates`, you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the `--safe-updates` option, `mysql` issues the following statement when it connects to the MySQL server:

```
SET SQL_SAFE_UPDATES=1,SQL_SELECT_LIMIT=1000, SQL_MAX_JOIN_SIZE=1000000;
```

See Section 13.5.3, "`SET` Syntax".

The `SET` statement has the following effects:

• You are not allowed to execute an `UPDATE` or `DELETE` statement unless you specify a key constraint in the `WHERE` clause or provide a `LIMIT` clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;

UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

• All large `SELECT` results are automatically limited to 1,000 rows unless the statement includes a `LIMIT` clause.

• Multiple-table `SELECT` statements that probably need to examine more than 1,000,000 row combinations are aborted.

To specify limits other than 1,000 and 1,000,000, you can override the defaults by using `--select_limit` and `--max_join_size` options:

```
shell> mysql --safe-updates --select_limit=500 --max_join_size=10000
```

8.3.4.3. Disabling `mysql` Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a query, it immediately and automatically tries to reconnect once to the server and send the query again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user and session variables. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id:    1
Current database: test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+------+
| a    |
+------+
| NULL |
+------+
1 row in set (0.05 sec)
```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` option.

8.4. mysqladmin — Client for Administering a MySQL Server

`mysqladmin` is a client for performing administrative operations. You can use it to check the server's configuration and current status, create and drop databases, and more.

Invoke `mysqladmin` like this:

```
shell> mysqladmin [options] command [command-options] [command [command-options
```

`mysqladmin` supports the following commands:

- `create db_name`

  Create a new database named `db_name`.

- `debug`

  Tell the server to write debug information to the error log.

- `drop db_name`

  Delete the database named `db_name` and all its tables.

- `extended-status`

  Display the server status variables and their values.

- `flush-hosts`

  Flush all information in the host cache.

- `flush-logs`

  Flush all logs.

- `flush-privileges`

  Reload the grant tables (same as `reload`).

- `flush-status`

  Clear status variables.

- `flush-tables`

  Flush all tables.

- `flush-threads`

  Flush the thread cache. (Added in MySQL 3.23.16.)

- `kill id,id,...`

  Kill server threads.

- `old-password new-password`

  This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. This command was added in MySQL 4.1.0.

- `password new-password`

Set a new password. This changes the password to `new-password` for the account that you use with `mysqladmin` for connecting to the server.

If *new-password* contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotes. On Windows, be sure to use double quotes rather than single quotes; single quotes are not be stripped from the password, they are interpreted as part of the password. For example:

shell> mysqladmin password "my new password"

- `ping`

  Check whether the server is alive. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. Beginning with MySQL 4.0.22, the status is 0 even in case of an error such as `Access denied`, because that means the server is running but disallowed the connection, which is different from the server not running.

- `processlist`

  Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`.

- `reload`

  Reload the grant tables.

- `refresh`

  Flush all tables and close and open log files.

- `shutdown`

  Stop the server.

- `start-slave`

  Start replication on a slave server. (Added in MySQL 3.23.16.)

- `status`

  Display a short server status message.

- `stop-slave`

  Stop replication on a slave server. (Added in MySQL 3.23.16.)

- `variables`

  Display the server system variables and their values.

- `version`

  Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
+----+-------+-----------+----+-------------+------+-------+------+
| Id | User  | Host      | db | Command     | Time | State | Info |
+----+-------+-----------+----+-------------+------+-------+------+
| 6  | monty | localhost |    | Processlist | 0    |       |      |
+----+-------+-----------+----+-------------+------+-------+------+
```

```
Uptime: 10077  Threads: 1  Questions: 9  Slow queries: 0
Opens: 6 Flush tables: 1  Open tables: 2
Memory in use: 1092K  Max memory used: 1116K
```

The `mysqladmin status` command result displays the following values:

- Uptime

  The number of seconds the MySQL server has been running.

- Threads

  The number of active threads (clients).

- Questions

  The number of questions (queries) from clients since the server was started.

- Slow queries

  The number of queries that have taken more than `long_query_time` seconds. See Section 5.10.5, "The Slow Query Log".

- Opens

  The number of tables the server has opened.

- Flush tables

  The number of `flush ...`, `refresh`, and `reload` commands the server has executed.

- Open tables

  The number of tables that currently are open.

- Memory in use

  The amount of memory allocated directly by `mysqld` code. This value is displayed only when MySQL has been compiled with `--with-debug=full`.

- Maximum memory used

  The maximum amount of memory allocated directly by `mysqld` code. This value is displayed only when MySQL has been compiled with `--with-debug=full`.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options:

- `--help, -?`

Display a help message and exit.

- `--character-sets-dir=path`

The directory where character sets are installed. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--count=num, -c num`

The number of iterations to make. This works only with `--sleep` (`-i`).

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysqladmin.trace'`.

- `--default-character-set=charset`

Use `charset` as the default character set. See Section 5.9.1, "The Character Set Used for Data and Sorting". Added in MySQL 4.1.9.

- `--force, -f`

Don't ask for confirmation for the `drop database` command. With multiple commands, continue even if an error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, you are prompted for one.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

The connection protocol to use. New in MySQL 4.1.

- `--relative, -r`

Show the difference between the current and previous values when used with `-i`. Currently, this option works only with the `extended-status` command.

- `--silent, -s`

Exit silently if a connection to the server cannot be established.

- `--sleep=delay, -i delay`

Execute commands again and again, sleeping for `delay` seconds in between.

- `--socket=path, -S path`

The socket file to use for the connection.

- `--user=user_name`, `-u user_name`

  The MySQL username to use when connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print out more information on what the program does.

- `--version`, `-V`

  Display version information and exit.

- `--vertical`, `-E`

  Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=count]`, `-w[count]`

  If the connection cannot be established, wait and retry instead of aborting. If an option value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--var_name=value` options:

-
  `connect_timeout`

  The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

-
  `shutdown_timeout`

  The maximum number of seconds to wait for shutdown. The default value is 3600 (1 hour).

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. However, this syntax is deprecated as of MySQL 4.0.

8.5. mysqlbinlog — Utility for Processing Binary Log Files

The binary log files that the server generates are written in binary format. To examine these files in text format, use the `mysqlbinlog` utility. It is available as of MySQL 3.23.14.

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log-file ...
```

For example, to display the contents of the binary log `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.0000003
```

The output includes all statements contained in `binlog.000003`, together with other information such as the time each statement took, the thread ID of the client that issued it, the timestamp when it was issued, and so forth.

Normally, you use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the `--read-from-remote-server` option.

When you read remote binary logs, the connection parameter options can be given to indicate how to connect to the server, but they are ignored unless you also specify the --read-from-remote-server option. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

You can also use `mysqlbinlog` to read relay log files written by a slave server in a replication setup. Relay logs have the same format as binary log files.

The binary log is discussed further in Section 5.10.4, "The Binary Log".

`mysqlbinlog` supports the following options:

- `--help, -?`

  Display a help message and exit.

- `--database=db_name, -d db_name`

  List entries for just this database (local log only).

- `--force-read, -f`

  With this option, if `mysqlbinlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mysqlbinlog` stops if it reads such an event.

- `--host=host_name, -h host_name`

  Get the binary log from the MySQL server on the given host.

- `--local-load=path, -l path`

  Prepare local temporary files for `LOAD DATA INFILE` in the specified directory.

- `--offset=N, -o N`

  Skip the first *N* entries.

- `--password[=password], -p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, you are prompted for one.

- `--port=port_num, -P port_num`

  The TCP/IP port number to use for connecting to a remote server.

- `--position=N, -j N`

  Deprecated, use `--start-position` instead (starting from MySQL 4.1.4).

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

  The connection protocol to use. New in MySQL 4.1.

- `--read-from-remote-server, -R`

  Read the binary log from a MySQL server. Any connection parameter options are ignored unless this option is given as well. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

- `--result-file=name, -r name`

Direct output to the given file.

- `--short-form`, `-s`

  Display only the statements contained in the log, without any extra information.

- `--socket=path`, `-S path`

  The socket file to use for the connection.

- `--start-datetime=datetime`

  Start reading the binary log at the first event having a datetime equal to or later than the `date-time` argument. The `datetime` value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

  ```
  shell> mysqlbinlog --start-datetime="2004-12-25 11:25:56" binlog.000003
  ```

  This option is available as of MySQL 4.1.4. It is useful for point-in-time recovery.

- `--stop-datetime=datetime`

  Stop reading the binary log at the first event having a datetime equal or posterior to the `date-time` argument. See the description of the `--start-datetime` option for information about the `datetime` value. This option is available as of MySQL 4.1.4. It is useful for point-in-time recovery.

- `--start-position=N`

  Start reading the binary log at the first event having a position equal to the `N` argument. Available as of MySQL 4.1.4 (previously named `--position`).

- `--stop-position=N`

  Stop reading the binary log at the first event having a position equal or greater than the `N` argument. Available as of MySQL 4.1.4.

- `--to-last-log`, `-t`

  Do not stop at the end of the requested binary log of the MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`. Available as of MySQL 4.1.2.

- `--disable-log-bin`, `-D`

  Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged. **Note**: This option requires that you have the `SUPER` privilege. Available as of MySQL 4.1.8.

- `--user=user_name`, `-u user_name`

  The MySQL username to use when connecting to a remote server.

- `--version`, `-V`

  Display version information and exit.

You can also set the following variable by using `--var_name=value` options:

-
    ```
    open_files_limit
    ```

    Specify the number of open file descriptors to reserve.

You can pipe the output of `mysqlbinlog` into a `mysql` client to execute the statements contained in the binary log. This is used to recover from a crash when you have an old backup (see Section 5.8.1, "Database Backups"):

```
shell> mysqlbinlog hostname-bin.000001 | mysql
```

Or:

```
shell> mysqlbinlog hostname-bin.[0-9]* | mysql
```

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you don't want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program.

`mysqlbinlog` has the `--position` option, which prints only those statements with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop or start when it sees an event of a given date and time. This enables you to perform point-in-time recovery using the `--stop-datetime` option (to be able to say, for example, "roll forward my databases to how they were today at 10:30 AM").

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog hostname-bin.000001 | mysql # DANGER!!
shell> mysqlbinlog hostname-bin.000002 | mysql # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a CREATE TEMPORARY TABLE statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports "unknown table."

To avoid problems like this, use a single connection to execute the contents of all binary logs that you want to process. Here is one way to do that:

```
shell> mysqlbinlog hostname-bin.000001 hostname-bin.000002 | mysql
```

Another approach is to do this:

```
shell> mysqlbinlog hostname-bin.000001 >  /tmp/statements.sql
shell> mysqlbinlog hostname-bin.000002 >> /tmp/statements.sql
shell> mysql -e "source /tmp/statements.sql"
```

In MySQL 3.23, the binary log did not contain the data to load for LOAD DATA INFILE statements. To execute such a statement from a binary log file, the original data file was needed. Starting from MySQL 4.0.14, the binary log does contain the data, so `mysqlbinlog` can produce output that reproduces the LOAD DATA INFILE operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a LOAD DATA LOCAL INFILE statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load` option.

Because `mysqlbinlog` converts LOAD DATA INFILE statements to LOAD DATA LOCAL

INFILE statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured to allow `LOCAL` capability. See Section 5.5.4, "Security Issues with `LOAD DATA LOCAL`".

Warning: The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `original_file_name-#-#`.

In the future, we will fix this problem by allowing `mysqlbinlog` to connect directly to a `mysqld` server. Then it is possible to safely remove the log files automatically as soon as the `LOAD DATA INFILE` statements have been executed.

Before MySQL 4.1, `mysqlbinlog` could not prepare output suitable for `mysql` if the binary log contained interlaced statements originating from different clients that used temporary tables of the same name. This is fixed in MySQL 4.1. However, the problem still existed for `LOAD DATA IN-FILE` statements until it was fixed in MySQL 4.1.8.

8.6. `mysqlcc`, the MySQL Control Center

`mysqlcc`, the MySQL Control Center, is a platform-independent client that provides a graphical user interface (GUI) to the MySQL database server. It supports interactive use, including syntax highlighting and tab completion. It provides database and table management, and allows server administration.

`mysqlcc` is deprecated and it is recommended that users choose the new MySQL Administrator and MySQL Query Browser, found at http://dev.mysql.com/downloads/.

Currently, `mysqlcc` runs on Windows and Linux platforms.

Invoke `mysqlcc` by double-clicking its icon in a graphical environment. From the command line, invoke it like this:

```
shell> mysqlcc [options]
```

`mysqlcc` supports the following options:

- `--help, -?`

    Display a help message and exit.

- `--blocking_queries, -b`

    Use blocking queries.

- `--compress, -C`

    Compress all information sent between the client and the server if both support compression.

- `--connection_name=name, -c name`

    This option is a synonym for `--server`.

- `--database=db_name, -d db_name`

    The database to use. This is useful mainly in an option file.

- `--history_size=size`, `-H size`

  The history size for the query window.

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--local-infile[={0|1}]`

  Enable or disable LOCAL capability for LOAD DATA INFILE. With no value, the option enables LOCAL. It may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable LOCAL. Enabling LOCAL has no effect if the server does not also support it.

- `--password[=password]`, `-p[password]`

  The password to use when connecting to the server. If you use the short option form (-p), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, you are prompted for one.

- `--plugins_path=name`, `-g name`

  The path to the directory where MySQL Control Center plugins are located.

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use for the connection.

- `--query`, `-q`

  Open a query window on startup.

- `--register`, `-r`

  Open the Register Server dialog on startup.

- `--server=name`, `-s name`

  The MySQL Control Center connection name.

- `--socket=path`, `-S path`

  The socket file to use for the connection.

- `--syntax`, `-y`

  Enable syntax highlighting and completion.

- `--syntax_file=name`, `-Y name`

  The syntax file for completion.

- --translations_path=*name*, -T *name*

  The path to the directory where MySQL Control Center translations are located.

- --user=*user_name*, -u *user_name*

  The MySQL username to use when connecting to the server.

- --version, -V

  Display version information and exit.

You can also set the following variables by using --*var_name*=*value* options:

- connect_timeout

  The number of seconds before connection timeout. (Default value is 0.)

- max_allowed_packet

  The maximum packet length to send to or receive from the server. (Default value is 16MB.)

- max_join_size

  The automatic limit for rows in a join. (Default value is 1,000,000.)

- net_buffer_length

  The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- select_limit

  The automatic limit for SELECT statements. (Default value is 1,000.)

It is also possible to set variables by using --set-variable=*var_name*=*value* or -O *var_name*=*value* syntax. However, this syntax is deprecated as of MySQL 4.0.

8.7. mysqlcheck — A Table Maintenance and Repair Program

The mysqlcheck client checks and repairs MyISAM tables. It can also optimize and analyze tables. mysqlcheck is available as of MySQL 3.23.38.

mysqlcheck is similar in function to myisamchk, but works differently. The main operational difference is that mysqlcheck must be used when the mysqld server is running, whereas myisamchk should be used when it is not. The benefit of using mysqlcheck is that you do not have to stop the server to check or repair your tables.

mysqlcheck uses the SQL statements CHECK TABLE, REPAIR TABLE, ANALYZE TABLE, and OPTIMIZE TABLE in a convenient way for the user. It determines which statements to use for the operation you want to perform, then sends the statements to the server to be executed.

There are three general ways to invoke mysqlcheck:

```
shell> mysqlcheck [options] db_name [tables]
shell> mysqlcheck [options] --databases DB1 [DB2 DB3...]
shell> mysqlcheck [options] --all-databases
```

If you don't name any tables or use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to the other clients. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables on command.

The following names can be used to change `mysqlcheck` default behavior:

`mysqlrepair`	The default option is `--repair`
`mysqlanalyze`	The default option is `--analyze`
`mysqloptimize`	The default option is `--optimize`

`mysqlcheck` supports the following options:

- `--help, -?`

  Display a help message and exit.

- `--all-databases, -A`

  Check all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

- `--all-in-1, -1`

  Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- `--analyze, -a`

  Analyze the tables.

- `--auto-repair`

  If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- `--character-sets-dir=path`

  The directory where character sets are installed. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--check, -c`

  Check the tables for errors.

- `--check-only-changed, -C`

  Check only tables that have changed since the last check or that haven't been closed properly.

- `--compress`

  Compress all information sent between the client and the server if both support compression.

- `--databases, -B`

  Process all tables in the named databases. With this option, all name arguments are regarded as

database names, not as table names.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`.

- `--default-character-set=charset`

  Use `charset` as the default character set. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--extended`, `-e`

  If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

  If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--fast`, `-F`

  Check only tables that haven't been closed properly.

- `--force`, `-f`

  Continue even if an SQL error occurs.

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--medium-check`, `-m`

  Do a check that is faster than an `--extended` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--optimize`, `-o`

  Optimize the tables.

- `--password[=password]`, `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, you are prompted for one.

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use for the connection.

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

  The connection protocol to use. New in MySQL 4.1.

- `--quick`, `-q`

  If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

  If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair`, `-r`

Do a repair that can fix almost anything except unique keys that aren't unique.

- `--silent, -s`

  Silent mode. Print only error messages.

- `--socket=`*path*`, -S `*path*

  The socket file to use for the connection.

- `--tables`

  Overrides the `--databases` or `-B` option. All arguments following the option are regarded as table names.

- `--user=`*user_name*`, -u `*user_name*

  The MySQL username to use when connecting to the server.

- `--verbose, -v`

  Verbose mode. Print information about the various stages of program operation.

- `--version, -V`

  Display version information and exit.

8.8. mysqldump — A Database Backup Program

The `mysqldump` client can be used to dump a database or a collection of databases for backup or for transferring the data to another SQL server (not necessarily a MySQL server). The dump contains SQL statements to create the table and/or populate the table.

If you are doing a backup on the server, and your tables all are `MyISAM` tables, you could consider using the `mysqlhotcopy` instead (faster backup, faster restore). See Section 8.9, "mysqlhotcopy — A Database Backup Program".

There are three general ways to invoke `mysqldump`:

```
shell> mysqldump [options] db_name [tables]
shell> mysqldump [options] --databases DB1 [DB2 DB3...]
shell> mysqldump [options] --all-databases
```

If you don't name any tables or use the `--databases` or `--all-databases` option, entire databases are dumped.

To get a list of the options your version of `mysqldump` supports, execute `mysqldump --help`.

If you run `mysqldump` without the `--quick` or `--opt` option, `mysqldump` loads the whole result set into memory before dumping the result. This probably is a problem if you are dumping a big database. As of MySQL 4.1, `--opt` is on by default, but can be disabled with `--skip-opt`.

If you are using a recent copy of the `mysqldump` program to generate a dump to be reloaded into a very old MySQL server, you should not use the `--opt` or `-e` options.

Before MySQL 4.1.2, out-of-range numeric values such as `-inf` and `inf`, as well as NaN (not-a-number) values are dumped by `mysqldump` as `NULL`. You can see this using the following sample table:

```
mysql> CREATE TABLE t (f DOUBLE);
mysql> INSERT INTO t VALUES(1e+111111111111111111111);
mysql> INSERT INTO t VALUES(-1e111111111111111111111);
mysql> SELECT f FROM t;
+------+
| f    |
+------+
|  inf |
| -inf |
+------+
```

For this table, `mysqldump` produces the following data output:

```
--
-- Dumping data for table `t`
--

INSERT INTO t VALUES (NULL);
INSERT INTO t VALUES (NULL);
```

The significance of this behavior is that if you dump and restore the table, the new table has contents that differ from the original contents. This problem is fixed as of MySQL 4.1.2; you cannot insert `inf` in the table, so this `mysqldump` behavior is only relevant when you deal with old servers.

`mysqldump` supports the following options:

- `--help, -?`

  Display a help message and exit.

- `--add-drop-database`

  Add a `DROP DATABASE` statement before each `CREATE DATABASE` statement. New in MySQL 4.1.13.

- `--add-drop-table`

  Add a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-locks`

  Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See Section 7.2.16, "Speed of `INSERT` Statements".

- `--all-databases, -A`

  Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

- `--allow-keywords`

  Allow creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--comments[={0|1}]`

  If set to `0`, suppresses additional information in the dump file such as program version, server version, and host. `--skip-comments` has the same effect as `--comments=0`. The default value is `1` to not suppress the extra information. New in MySQL 4.0.17.

- `--compact`

Produce less verbose output. This option suppresses comments and enables the `--skip-add-drop-table`, `--no-set-names`, `--skip-disable-keys`, and `--skip-add-locks` options. New in MySQL 4.1.2.

- `--compatible=name`

Produce output that is compatible with other database systems or with older MySQL servers. The value of `name` can be `ansi`, `mysql323`, `mysql40`, `postgresql`, `oracle`, `mssql`, `db2`, `maxdb`, `no_key_options`, `no_table_options`, or `no_field_options`. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See Section 5.3.2, "The Server SQL Mode".

This option requires a server version of 4.1.0 or higher. With older servers, it does nothing.

- `--complete-insert, -c`

Use complete `INSERT` statements that include column names.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--create-options`

Include all MySQL-specific table options in the `CREATE TABLE` statements. Before MySQL 4.1.2, use `--all` instead.

- `--databases, -B`

Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE IF NOT EXISTS db_name` and `USE db_name` statements are included in the output before each new database.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`.

- `--default-character-set=charset`

Use `charset` as the default character set. See Section 5.9.1, "The Character Set Used for Data and Sorting". If not specified, `mysqldump` from MySQL 4.1.2 or later uses `utf8`, and earlier versions use `latin1`.

- `--delayed-insert`

Insert rows using `INSERT DELAYED` statements. This option was disabled in MySQL 5.0.7.

- `--delete-master-logs`

On a master replication server, delete the binary logs after performing the dump operation. This option automatically enables `--first-slave` before MySQL 4.1.8 and enables `--master-data` thereafter. It was added in MySQL 3.23.57 (for MySQL 3.23) and MySQL 4.0.13 (for MySQL 4.0).

- `--disable-keys, -K`

For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file into a MySQL 4.0 server faster because the indexes are created after all rows are inserted. This option is effective only for `MyISAM` tables.

- `--extended-insert`, `-e`

  Use multiple-row `INSERT` syntax that include several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`, `--lines-terminated-by=...`

  These options are used with the `-T` option and have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See Section 13.2.5, "`LOAD DATA INFILE` Syntax".

- `--first-slave`, `-x`

  Deprecated, renamed to `--lock-all-tables` in MySQL 4.1.8.

- `--flush-logs`, `-F`

  Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. Note that if you use this option in combination with the `--all-databases` (or `-A`) option, the logs are flushed *for each database dumped*. The exception is when using `--lock-all-tables` or `--master-data`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with either `--lock-all-tables` or `--master-data`.

- `--force`, `-f`

  Continue even if an SQL error occurs during a table dump.

- `--host=host_name`, `-h host_name`

  Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--hex-blob`

  Dump binary string columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected columns are `BINARY`, `VARBINARY`, and `BLOB` in MySQL 4.1 and up, and `CHAR BINARY`, `VARCHAR BINARY`, and `BLOB` in MySQL 4.0. This option was added in MySQL 4.0.23 and 4.1.8.

- `--lock-all-tables`, `-x`

  Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`. Added in MySQL 4.1.8.

- `--lock-tables`, `-l`

  Lock all tables before starting the dump. The tables are locked with `READ LOCAL` to allow concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB` and `BDB`, `--single-transaction` is a much better option, because it does not need to lock the tables at all.

  Please note that when dumping multiple databases, `--lock-tables` locks tables for each database separately. So, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

- `--master-data[=value]`

  This option causes the binary log position and filename to be written to the output. This option requires the `RELOAD` privilege and the binary log must be enabled. If the option value is equal to 1, the position and filename are written to the dump output in the form of a `CHANGE MASTER`

statement that makes a slave server start from the correct position in the master's binary logs if you use this SQL dump of the master to set up a slave. If the option value is equal to 2, the CHANGE MASTER statement is written as an SQL comment. This is the default action if `value` is omitted. `value` may be given as of MySQL 4.1.8; before that, do not specify an option value.

The --master-data option turns on --lock-all-tables, unless --single-transaction also is specified (in which case, a global read lock is only acquired a short time at the beginning of the dump. See also the description for --single-transaction. In all cases, any action on logs happens at the exact moment of the dump. This option automatically turns off --lock-tables.

- --no-create-db, -n

This option suppresses the CREATE DATABASE /*!32312 IF NOT EXISTS*/ db_name statements that are otherwise included in the output if the --databases or --all-databases option is given.

- --no-create-info, -t

Don't write CREATE TABLE statements that re-create each dumped table.

- --no-data, -d

Don't write any row information for the table. This is very useful if you just want to get a dump of the structure for a table.

- --opt

This option is shorthand; it is the same as specifying --add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset. It should give you a fast dump operation and produce a dump file that can be reloaded into a MySQL server quickly. **As of MySQL 4.1, --opt is on by default, but can be disabled with --skip-opt**. To disable only certain of the options enabled by --opt, use their --skip forms; for example, --skip-add-drop-table or --skip-quick.

- --password[=password], -p[password]

The password to use when connecting to the server. If you use the short option form (-p), you *cannot* have a space between the option and the password. If you omit the `password` value following the --password or -p option on the command line, you are prompted for one.

- --port=port_num, -P port_num

The TCP/IP port number to use for the connection.

- --protocol={TCP | SOCKET | PIPE | MEMORY}

The connection protocol to use. New in MySQL 4.1.

- --quick, -q

This option is useful for dumping large tables. It forces mysqldump to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- --quote-names, -Q

Quote database, table, and column names within '`' characters. If the server SQL mode includes the ANSI_QUOTES option, names are quoted within '"' characters. As of MySQL 4.1.1, --quote-names is on by default, but can be disabled with --skip-quote-names.

- --result-file=file, -r file

Direct output to a given file. This option should be used on Windows, because it prevents newline '\n' characters from being converted to '\r\n' carriage return/newline sequences.

- `--set-charset`

  Add `SET NAMES` *default_character_set* to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset`. This option was added in MySQL 4.1.2.

- `--single-transaction`

  This option issues a `BEGIN` SQL statement before dumping data from the server. It is useful only with transactional tables such as `InnoDB` and `BDB`, because then it dumps the consistent state of the database at the time when `BEGIN` was issued without blocking any applications.

  When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `HEAP` tables dumped while using this option may still change state.

  The `--single-transaction` option was added in MySQL 4.0.2. This option is mutually exclusive with the `--lock-tables` option, because `LOCK TABLES` causes any pending transactions to be committed implicitly.

  To dump big tables, you should combine this option with `--quick`.

- `--socket=`*path*, `-S` *path*

  The socket file to use when connecting to `localhost` (which is the default host).

- `--skip-comments`

  See the description for the `--comments` option.

- `--tab=`*path*, `-T` *path*

  Produce tab-separated data files. For each dumped table, `mysqldump` creates a *tbl_name*`.sql` file that contains the `CREATE TABLE` statement that creates the table, and a *tbl_name*`.txt` file that contains its data. The option value is the directory in which to write the files.

  By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-`*xxx* and `--lines--`*xxx* options.

  Note: This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. You must have the `FILE` privilege, and the server must have permission to write files in the directory that you specify.

- `--tables`

  Override the `--databases` or `-B` option. All arguments following the option are regarded as table names.

- `--triggers`

  Dump triggers for each dumped table. This option is on by default; disable it with `--skip-triggers`. This option was added in MySQL 5.0.11. Before that, triggers are not dumped.

- `--user=`*user_name*, `-u` *user_name*

  The MySQL username to use when connecting to the server.

- `--verbose, -v`

  Verbose mode. Print out more information on what the program does.

- `--version, -V`

  Display version information and exit.

- `--where='`*`where-condition`*`', -w '`*`where-condition`*`'`

  Dump only records selected by the given WHERE condition. Note that quotes around the condition are mandatory if it contains spaces or characters that are special to your command interpreter.

  Examples:

  ```
  "--where=user='jimf'"
  "-wuserid>1"
  "-wuserid<1"
  ```

- `--xml, -X`

  Write dump output as well-formed XML.

You can also set the following variables by using `--`*`var_name`*`=`*`value`* options:

- `max_allowed_packet`

  The maximum size of the buffer for client/server communication. The value of the variable can be up to 16MB before MySQL 4.0, and up to 1GB from MySQL 4.0 on.

- `net_buffer_length`

  The initial size of the buffer for client/server communication. When creating multiple-row-insert statements (as with option `--extended-insert` or `--opt`), mysqldump creates rows up to `net_buffer_length` length. If you increase this variable, you should also ensure that the `net_buffer_length` variable in the MySQL server is at least this large.

It is also possible to set variables by using `--set-variable=`*`var_name`*`=`*`value`* or `-O` *`var_name`*`=`*`value`* syntax. However, this syntax is deprecated as of MySQL 4.0.

The most common use of mysqldump is probably for making a backup of an entire database:

```
shell> mysqldump --opt db_name > backup-file.sql
```

You can read the dump file back into the server like this:

```
shell> mysql db_name < backup-file.sql
```

Or like this:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

mysqldump is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

It is possible to dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

If you want to dump all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > all_databases.sql
```

If tables are stored in the `InnoDB` storage engine, `mysqldump` provides a way of making an online backup of these (see command below). This backup just needs to acquire a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and lock is released. So if and only if one long updating statement is running when the `FLUSH...` is issued, the MySQL server may get stalled until that long statement finishes, and then the dump becomes lock-free. So if the MySQL server receives only short (in the sense of "short execution time") updating statements, even if there are plenty of them, the initial lock period should not be noticeable.

```
shell> mysqldump --all-databases --single-transaction > all_databases.sql
```

For point-in-time recovery (also known as "roll-forward", when you need to restore an old backup and replay the changes which happened since that backup), it is often useful to rotate the binary log (see Section 5.10.4, "The Binary Log") or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
or
shell> mysqldump --all-databases --flush-logs --master-data=2 > all_databases.s
```

The simultaneous use of `--master-data` and `--single-transaction` works as of MySQL 4.1.8. It provides a convenient way to make an online backup suitable for point-in-time recovery, if tables are stored in the `InnoDB` storage engine.

For more information on making backups, see Section 5.8.1, "Database Backups".

8.9. mysqlhotcopy — A Database Backup Program

`mysqlhotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses `LOCK TABLES`, `FLUSH TABLES`, and `cp` or `scp` to quickly make a backup of a database. It's the fastest way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mysqlhotcopy` works only for backing up `MyISAM` and `ISAM` tables. It runs on Unix, and as of MySQL 4.0.18 also on NetWare.

```
shell> mysqlhotcopy db_name [/path/to/new_directory]
```

```
shell> mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mysqlhotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde ('~'):

```
shell> mysqlhotcopy db_name./~regex/
```

`mysqlhotcopy` supports the following options:

- `--help`, `-?`

  Display a help message and exit.

- `--allowold`

  Don't abort if target exists (rename it by adding an `_old` suffix).

- `--checkpoint=db_name.tbl_name`

  Insert checkpoint entries into the specified `db_name.tbl_name`.

- `--debug`

  Enable debug output.

- `--dryrun`, `-n`

  Report actions without doing them.

- `--flushlog`

  Flush logs after all tables are locked.

- `--keepold`

  Don't delete previous (renamed) target when done.

- `--method=command`

  Method for copy (`cp` or `scp`).

- `--noindices`

  Don't include full index files in the backup. This makes the backup smaller and faster. The indexes can be reconstructed later with `myisamchk -rq` for `MyISAM` tables or `isamchk -rq` for `ISAM` tables.

- `--password=password`, `-ppassword`

  The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use when connecting to the local server.

- `--quiet`, `-q`

  Be silent except for errors.

- `--regexp=expr`

  Copy all databases with names matching the given regular expression.

- `--socket=path`, `-S path`

  The Unix socket file to use for the connection.

- `--suffix=str`

  The suffix for names of copied databases.

- `--tmpdir=path`

  The temporary directory (instead of `/tmp`).

- `--user=user_name`, `-u user_name`

  The MySQL username to use when connecting to the server.

`mysqlhotcopy` reads the `[client]` and `[mysqlhotcopy]` option groups from option files.

To execute `mysqlhotcopy`, you must have access to the files for the tables that you are backing up, the `SELECT` privilege for those tables, and the `RELOAD` privilege (to be able to execute `FLUSH TABLES`).

Use `perldoc` for additional `mysqlhotcopy` documentation:

```
shell> perldoc mysqlhotcopy
```

8.10. mysqlimport — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA INFILE` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA INFILE`. See Section 13.2.5, "`LOAD DATA INFILE` Syntax".

Invoke `mysqlimport` like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the filename and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options:

- `--help`, `-?`

  Display a help message and exit.

- `--columns=column_list`, `-c column_list`

  This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match up data file columns with table columns.

- `--compress`, `-C`

  Compress all information sent between the client and the server if both support compression.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`.

- `--delete`, `-D`

  Empty the table before importing the text file.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`, `--lines-terminated-by=...`

These options have the same meaning as the corresponding clauses for LOAD DATA INFILE. See Section 13.2.5, "LOAD DATA INFILE Syntax".

- --force, -f

  Ignore errors. For example, if a table for a text file doesn't exist, continue processing any remaining files. Without --force, mysqlimport exits if a table doesn't exist.

- --host=*host_name*, -h *host_name*

  Import data to the MySQL server on the given host. The default host is localhost.

- --ignore, -i

  See the description for the --replace option.

- --ignore-lines=*n*

  Ignore the first *n* lines of the data file.

- --local, -L

  Read input files locally from the client host.

- --lock-tables, -l

  Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- --password[=*password*], -p[*password*]

  The password to use when connecting to the server. If you use the short option form (-p), you *cannot* have a space between the option and the password. If you omit the *password* value following the --password or -p option on the command line, you are prompted for one.

- --port=*port_num*, -P *port_num*

  The TCP/IP port number to use for the connection.

- --protocol={TCP | SOCKET | PIPE | MEMORY}

  The connection protocol to use. New in MySQL 4.1.

- --replace, -r

  The --replace and --ignore options control handling of input records that duplicate existing records on unique key values. If you specify --replace, new rows replace existing rows that have the same unique key value. If you specify --ignore, input rows that duplicate an existing row on a unique key value are skipped. If you don't specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- --silent, -s

  Silent mode. Produce output only when errors occur.

- --socket=*path*, -S *path*

  The socket file to use when connecting to localhost (which is the default host).

- --user=*user_name*, -u *user_name*

  The MySQL username to use when connecting to the server.

- `--verbose, -v`

  Verbose mode. Print out more information what the program does.

- `--version, -V`

  Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE imptest(id INT, n VARCHAR(30))' test
shell> ed
a
100     Max Sydow
101     Count Dracula
.
w imptest.txt
32
q
shell> od -c imptest.txt
0000000   1   0   0  \t   M   a   x           S   y   d   o   w  \n   1   0
0000020   1  \t   C   o   u   n   t           D   r   a   c   u   l   a  \n
0000040
shell> mysqlimport --local test imptest.txt
test.imptest: Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
shell> mysql -e 'SELECT * FROM imptest' test
+------+---------------+
| id   | n             |
+------+---------------+
|  100 | Max Sydow     |
|  101 | Count Dracula |
+------+---------------+
```

8.11. mysqlshow — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly look at which databases exist, their tables, and a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program. See Section 13.5.4, "`SHOW` Syntax".

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, all matching databases are shown.

- If no table is given, all matching tables in the database are shown.

- If no column is given, all matching columns and column types in the table are shown.

Note that in newer MySQL versions, you see only those database, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters ('*', '?', '%', or '_'), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) in order to get a list of the

proper tables or columns. '*' and '?' characters are converted into SQL '%' and '_' wildcard characters. This might cause some confusion when you try to display the columns for a table with a '_' in the name, because in this case `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra '%' last on the command line as a separate argument.

`mysqlshow` supports the following options:

- `--help, -?`

  Display a help message and exit.

- `--character-sets-dir=path`

  The directory where character sets are installed. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--compress, -C`

  Compress all information sent between the client and the server if both support compression.

- `--debug[=debug_options], -# [debug_options]`

  Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`.

- `--default-character-set=charset`

  Use `charset` as the default character set. See Section 5.9.1, "The Character Set Used for Data and Sorting".

- `--host=host_name, -h host_name`

  Connect to the MySQL server on the given host.

- `--keys, -k`

  Show table indexes.

- `--password[=password], -p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, you are prompted for one.

- `--port=port_num, -P port_num`

  The TCP/IP port number to use for the connection.

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

  The connection protocol to use. New in MySQL 4.1.

- `--show-table-type`

  Show a column indicating the table type, as in `SHOW FULL TABLES`. New in MySQL 5.0.4.

- `--socket=path, -S path`

  The socket file to use when connecting to `localhost` (which is the default host).

- `--status, -i`

  Display extra information about each table.

- `--user=user_name, -u user_name`

The MySQL username to use when connecting to the server.

- `--verbose, -v`

  Verbose mode. Print out more information what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

  Display version information and exit.

8.12. perror — Explain Error Codes

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by either examining the documentation for your system or by using the `perror` utility.

`perror` prints a description for a system error code or for a storage engine (table handler) error code.

Invoke `perror` like this:

```
shell> perror [options] errorcode ...
```

Example:

```
shell> perror 13 64
Error code  13:  Permission denied
Error code  64:  Machine is not on the network
```

Note: To obtain the error message for a MySQL Cluster error code, invoke `perror` with the `--ndb` option:

```
shell> perror --ndb  errorcode
```

Note that the meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

8.13. replace — A String-Replacement Utility

The `replace` utility program changes strings in place in files or on the standard input. It uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps `a` and `b` in the given files, `file1` and `file2`:

```
shell> replace a b b a -- file1 file2 ...
```

Use the `--` option to indicate where the string-replacement list ends and the filenames begin.

Any file named on the command line is modified in place, so you may want to make a copy of the original before converting it.

If no files are named on the command line, `replace` reads the standard input and writes to the standard output. In this case, no `--` option is needed.

The `replace` program is used by `msql2mysql`. See Section 23.9.1, "msql2mysql — Convert mSQL Programs for Use with MySQL".

`replace` supports the following options:

- `-?,-I`

  Display a help message and exit.

- `-# debug_options`

  Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`.

- `-s`

  Silent mode. Print out less information what the program does.

- `-v`

  Verbose mode. Print out more information what the program does.

- `-V`

  Display version information and exit.

Chapter 9. Language Structure

This chapter discusses the rules for writing the following elements of SQL statements when using MySQL:

- Literal values such as strings and numbers

- Identifiers such as table and column names

- User and system variables

- Comments

- Reserved words

9.1. Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal values, boolean values, and `NULL`. The section also covers the various nuances and "gotchas" that you may run into when dealing with these basic types in MySQL.

9.1.1. Strings

A string is a sequence of characters, surrounded by either single quote ('') or double quote ('"') characters. Examples:

```
'a string'
"another string"
```

If the server SQL mode has `ANSI_QUOTES` enabled, string literals can be quoted only with single quotes. A string quoted with double quotes is interpreted as an identifier.

As of MySQL 4.1.1, string literals may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

For more information about these forms of string syntax, see Section 10.3.7, "Character String Literal Character Set and Collation".

Within a string, certain sequences have special meaning. Each of these sequences begins with a backslash ('\'), known as the *escape character*. MySQL recognizes the following escape sequences:

\0	An ASCII 0 (NUL) character.
\'	A single quote ('') character.
\"	A double quote ('"') character.
\b	A backspace character.
\n	A newline (linefeed) character.

\r	A carriage return character.
\t	A tab character.
\Z	ASCII 26 (Control-Z). This character can be encoded as '\Z' to allow you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. (ASCII 26 causes problems if you try to use mysql *db_name* < *file_name*.)
\\	A backslash ('\') character.
\%	A '%' character. See note following table.
_	A '_' character. See note following table.

These sequences are case sensitive. For example, '\b' is interpreted as a backspace, but '\B' is interpreted as 'B'.

The '\%' and '_' sequences are used to search for literal instances of '%' and '_' in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See Section 12.3.1, "String Comparison Functions". Note that if you use '\%' or '_' in other contexts, they return the strings '\%' and '_' and not '%' and '_'.

In all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped.

There are several ways to include quotes within a string:

- A ''' inside a string quoted with ''' may be written as ''''.

- A '"' inside a string quoted with '"' may be written as '""'.

- You can precede the quote character with an escape character ('\').

- A ''' inside a string quoted with '"' needs no special treatment and need not be doubled or escaped. In the same way, '"' inside a string quoted with ''' needs no special treatment.

The following SELECT statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', '"hello"', '""hello""', 'hel''lo', '\'hello';
+-------+---------+-----------+--------+--------+
| hello | "hello" | ""hello"" | hel'lo | 'hello |
+-------+---------+-----------+--------+--------+

mysql> SELECT "hello", "'hello'", "''hello''", "hel""lo", "\"hello";
+-------+---------+-----------+--------+--------+
| hello | 'hello' | ''hello'' | hel"lo | "hello |
+-------+---------+-----------+--------+--------+

mysql> SELECT 'This\nIs\nFour\nLines';
+--------------------+
| This
Is
Four
Lines |
+--------------------+

mysql> SELECT 'disappearing\ backslash';
+------------------------+
| disappearing backslash |
+------------------------+
```

If you want to insert binary data into a string column (such as a BLOB), the following characters must be represented by escape sequences:

NUL	NUL byte (ASCII 0). Represent this character by '\0' (a backslash followed by an ASCII '0' character).
\	Backslash (ASCII 92). Represent this character by '\\'.
'	Single quote (ASCII 39). Represent this character by '\''.
"	Double quote (ASCII 34). Represent this character by '\"'.

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. For example, in a C program, you can use the `mysql_real_escape_string()` C API function to escape characters. See Section 23.2.3.48, "`mysql_real_escape_string()`". The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See Section 23.4, "MySQL Perl API".

- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that allows you to insert special markers into a query string, and then bind data values to them when you issue the query. In this case, the API takes care of escaping special characters in the values for you.

9.1.2. Numbers

Integers are represented as a sequence of digits. Floats use '.' as a decimal separator. Either type of number may be preceded by '-' to indicate a negative value.

Examples of valid integers:

```
1221
0
-32
```

Examples of valid floating-point numbers:

```
294.42
-32032.6809e+10
148.00
```

An integer may be used in a floating-point context; it is interpreted as the equivalent floating-point number.

9.1.3. Hexadecimal Values

MySQL supports hexadecimal values. In numeric contexts, these act like integers (64-bit precision). In string contexts, these act like binary strings, where each pair of hex digits is converted to a character:

```
mysql> SELECT x'4D7953514C';
        -> 'MySQL'
mysql> SELECT 0xa+0;
        -> 10
mysql> SELECT 0x5061756c;
        -> 'Paul'
```

In MySQL 4.1 (and in MySQL 4.0 when using the `--new` option), the default type of a hexadecimal value is a string. If you want to ensure that the value is treated as a number, you can use

```
CAST(... AS UNSIGNED):

mysql> SELECT 0x41, CAST(0x41 AS UNSIGNED);
        -> 'A', 65
```

The `0x` syntax is based on ODBC. Hexadecimal strings are often used by ODBC to supply values for `BLOB` columns. The `x'hexstring'` syntax is new in 4.0 and is based on standard SQL.

Beginning with MySQL 4.0.1, you can convert a string or a number to a string in hexadecimal format with the `HEX()` function:

```
mysql> SELECT HEX('cat');
        -> '636174'
mysql> SELECT 0x636174;
        -> 'cat'
```

9.1.4. Boolean Values

Beginning with MySQL 4.1, the constant `TRUE` evaluates to `1` and the constant `FALSE` evaluates to `0`. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
        -> 1, 1, 0, 0
```

9.1.5. Bit-Field Values

Beginning with MySQL 5.0.3, bit-field values can be written using `b'value'` notation. `value` is a binary value written using 0s and 1s.

Bit-field notation is convenient for specifying values to be assigned to `BIT` columns:

```
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
+------+----------+----------+----------+
| b+0  | BIN(b+0) | OCT(b+0) | HEX(b+0) |
+------+----------+----------+----------+
|  255 | 11111111 | 377      | FF       |
|   10 | 1010     | 12       | A        |
+------+----------+----------+----------+
```

9.1.6. `NULL` Values

The `NULL` value means "no data." `NULL` can be written in any lettercase.

Be aware that the `NULL` value is different from values such as `0` for numeric types or the empty string for string types. See Section A.5.3, "Problems with `NULL` Values".

For text file import or export operations performed with `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, `NULL` is represented by the `\N` sequence. See Section 13.2.5, "`LOAD DATA INFILE` Syntax".

9.2. Database, Table, Index, Column, and Alias Names

Database, table, index, column, and alias names are identifiers. This section describes the allowable syntax for identifiers in MySQL.

The following table describes the maximum length and allowable characters for each type of identifier.

Identifier	Maximum Length (bytes)	Allowed Characters
Database	64	Any character that is allowed in a directory name, except '/', '\', or '.'
Table	64	Any character that is allowed in a filename, except '/', '\', or '.'
Column	64	All characters
Index	64	All characters
Alias	255	All characters

In addition to the restrictions noted in the table, no identifier can contain ASCII 0 or a byte with a value of 255. Database, table, and column names should not end with space characters. Before MySQL 4.1, identifier quote characters should not be used in identifiers.

Beginning with MySQL 4.1, identifiers are stored using Unicode (UTF8). This applies to identifiers in table definitions that stored in `.frm` files and to identifiers stored in the grant tables in the `mysql` database. Although Unicode identifiers can include multi-byte characters, note that the maximum lengths shown in the table are byte counts until MySQL 4.1.5; until that version, if an identifier does contain multi-byte characters, the number of *characters* allowed in the identifier is less than the value shown in the table.

An identifier may be quoted or unquoted. If an identifier is a reserved word or contains special characters, you *must* quote it whenever you refer to it. For a list of reserved words, see Section 9.6, "Treatment of Reserved Words in MySQL". Special characters are those outside the set of alphanumeric characters from the current character set, '_', and '$'.

The identifier quote character is the backtick ('`'):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the server SQL mode includes the `ANSI_QUOTES` mode option, it is also allowable to quote identifiers with double quotes:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax. (...)
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

See Section 5.3.2, "The Server SQL Mode".

As of MySQL 4.1, identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, double the character. The following statement creates a table named `a`b` that contains a column named `c"d`:

```
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

Identifier quoting was introduced in MySQL 3.23.6 to allow use of identifiers that are reserved words or that contain special characters. Before 3.23.6, you cannot use identifiers that require quotes, so the rules for legal identifiers are more restrictive:

- A name may consist of alphanumeric characters from the current character set, '_', and '$'. The default character set is cp1252 (Latin1). This may be changed with the –

-default-character-set option to mysqld. See Section 5.9.1, "The Character Set Used for Data and Sorting".

• A name may start with any character that is legal in a name. In particular, a name may start with a digit; this differs from many other database systems! However, an unquoted name cannot consist *only* of digits.

• You cannot use the '.' character in names because it is used to extend the format by which you can refer to columns (see Section 9.2.1, "Identifier Qualifiers").

It is recommended that you do not use names of the pattern *XeX*, such as 1e or 2e2, because an expression like 1e+1 is ambiguous. It might be interpreted as the expression 1e + 1 or as the number 1e+1, depending on context.

Be careful when using MD5 to produce table names, as it can produce illegal tables names such as the ones listed above.

9.2.1. Identifier Qualifiers

MySQL allows names that consist of a single identifier or multiple identifiers. The components of a multiple-part name should be separated by period ('.') characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which the final identifier is interpreted.

In MySQL you can refer to a column using any of the following forms:

Column Reference	Meaning
col_name	The column col_name from whichever table used in the query contains a column of that name.
tbl_name.col_name	The column col_name from table tbl_name of the default database.
db_name.tbl_name.col_name	The column col_name from table tbl_name of the database db_name. This syntax is unavailable before MySQL 3.22.

If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, `my-table`.`my-column` is legal, whereas `my-table.my-column` is not.

You need not specify a tbl_name or db_name.tbl_name prefix for a column reference in a statement unless the reference would be ambiguous. Suppose that tables t1 and t2 each contain a column c, and you retrieve c in a SELECT statement that uses both t1 and t2. In this case, c is ambiguous because it is not unique among the tables used in the statement. You must qualify it with a table name as t1.c or t2.c to indicate which table you mean. Similarly, to retrieve from a table t in database db1 and from a table t in database db2 in the same statement, you must refer to columns in those tables as db1.t.col_name and db2.t.col_name.

A word that follows a period in a qualified name must be an identifier, so it is not necessary to quote it, even if it is a reserved word.

The syntax .tbl_name means the table tbl_name in the current database. This syntax is accepted for ODBC compatibility because some ODBC programs prefix table names with a '.' character.

9.2.2. Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Tables within a database correspond to at least one file within the database directory (and possibly more, depending on the storage engine). Consequently, the case sensitivity of the underlying operating system determines the case sensitivity of database and table names. This means database and table names are not case sensitive in Windows, and case sensitive in most varieties of Unix. One notable exception is Mac

OS X, which is Unix-based but uses a default filesystem type (HFS+) that is not case sensitive. However, Mac OS X also supports UFS volumes, which are case sensitive just as on any Unix. See Section 1.8.4, "MySQL Extensions to Standard SQL".

Note: Although database and table names are not case sensitive on some platforms, you should not refer to a given database or table using different cases within the same query. The following query would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column, index, stored routine, and trigger names are not case sensitive on any platform, nor are column aliases.

Table aliases are case sensitive before MySQL 4.1.1. The following query would not work because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
    -> WHERE a.col_name = 1 OR A.col_name = 2;
```

If you have trouble remembering the allowable lettercase for database and table names, adopt a consistent convention, such as always creating databases and tables using lowercase names.

How table and database names are stored on disk and used in MySQL is defined by the `lower_case_table_names` system variable, which you can set when starting `mysqld`. `lower_case_table_names` can take one of the following values:

Value	Meaning
0	Table and database names are stored on disk using the lettercase specified in the `CREATE TABLE` or `CREATE DATABASE` statement. Name comparisons are case sensitive. This is the default on Unix systems. Note that if you force this to 0 with `--lower-case-table-names=0` on a case-insensitive filesystem and access `MyISAM` tablenames using different lettercases, this may lead to index corruption.
1	Table names are stored in lowercase on disk and name comparisons are not case sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names as of MySQL 4.0.2, and to table aliases as of 4.1.1. This value is the default on Windows and Mac OS X systems.
2	Table and database names are stored on disk using the lettercase specified in the `CREATE TABLE` or `CREATE DATABASE` statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case sensitive. **Note**: This works *only* on filesystems that are not case sensitive! `InnoDB` table names are stored in lowercase, as for `lower_case_table_names=1`. Setting `lower_case_table_names` to 2 can be done as of MySQL 4.0.18.

On Windows, the default value of `lower_case_table_names` is 1. On Mac OS X, the default is 1 before MySQL 4.0.18 and 2 as of 4.0.18.

If you are using MySQL on only one platform, you don't normally have to change the `lower_case_table_names` variable. However, you may encounter difficulties if you want to transfer tables between platforms that differ in filesystem case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows those names are considered the same. To avoid data transfer problems stemming from database or table name lettercase, you have two options:

- Use `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you don't see the names in their original lettercase.

- Use `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on

Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your queries always refer to your database and table names with the correct lettercase on Windows. If you transfer your queries to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

Exception: If you are using `InnoDB` tables, you should set `lower_case_table_names` to 1 on all platforms to force names to be converted to lowercase.

Note that before setting `lower_case_table_names` to 1 on Unix, you must first convert your old database and table names to lowercase before restarting `mysqld`.

9.3. User Variables

MySQL supports user variables as of version 3.23.6. You can store a value in a user variable and refer to it later, which allows you to pass values from one statement to another. User variables are connection-specific. That is, a variable defined by one client cannot be seen or used by other clients. All variables for a client connection are automatically freed when the client exits.

User variables are written as `@var_name`, where the variable name `var_name` may consist of alphanumeric characters from the current character set, '.', '_', and '$'. The default character set is cp1252 (Latin1). This may be changed with the `--default-character-set` option to `mysqld`. See Section 5.9.1, "The Character Set Used for Data and Sorting". User variable names are not case sensitive beginning with MySQL 5.0. Before that, they are case sensitive.

One way to set a user variable is by issuing a `SET` statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For `SET`, either `=` or `:=` can be used as the assignment operator. The `expr` assigned to each variable can evaluate to an integer, real, string, or `NULL` value.

You can also assign a value to a user variable in statements other than `SET`. In this case, the assignment operator must be `:=` and not `=` because `=` is treated as a comparison operator in non-`SET` statements:

```
mysql> SET @t1=0, @t2=0, @t3=0;
mysql> SELECT @t1:=(@t2:=1)+@t3:=4,@t1,@t2,@t3;
+----------------------+------+------+------+
| @t1:=(@t2:=1)+@t3:=4 | @t1  | @t2  | @t3  |
+----------------------+------+------+------+
|                    5 |    5 |    1 |    4 |
+----------------------+------+------+------+
```

User variables may be used where expressions are allowed. This does not currently include contexts that explicitly require a literal value, such as in the `LIMIT` clause of a `SELECT` statement, or the `IGNORE number LINES` clause of a `LOAD DATA` statement.

If you refer to a variable that has not been initialized, its value is `NULL`.

Beginning with MySQL 4.1.1, if a user variable is assigned a string value, it also has the same character set and collation as the string. The coercibility of user variables is "implicit" as of MySQL 4.1.11 and 5.0.3. (This is the same coercibility as table column values.)

Note: In a `SELECT` statement, each expression is evaluated only when sent to the client. This means that in a `HAVING`, `GROUP BY`, or `ORDER BY` clause, you cannot refer to an expression that involves variables that are set in the `SELECT` list. For example, the following statement does *not* work as expected:

```
mysql> SELECT (@aa:=id) AS a, (@aa+3) AS b FROM tbl_name HAVING b=5;
```

The reference to b in the HAVING clause refers to an alias for an expression in the SELECT list that uses @aa. This does not work as expected: @aa does not contain the value of the current row, but the value of id from the previous selected row.

The general rule is to never assign a value to a user variable in one part of a statement *and* use the same variable in some other part the same statement. You might get the results you expect, but this is not guaranteed.

Another issue with setting a variable and using it in the same statement is that the default result type of a variable is based on the type of the variable at the start of the statement. The following example illustrates this:

```
mysql> SET @a='test';
mysql> SELECT @a,(@a:=20) FROM tbl_name;
```

For this SELECT statement, MySQL reports to the client that column one is a string and converts all accesses of @a to strings, even though @a is set to a number for the second row. After the SELECT statement executes, @a is regarded as a number for the next statement.

To avoid problems with this behavior, either do not set and use the same variable within a single statement, or else set the variable to 0, 0.0, or ' ' to define its type before you use it.

An unassigned variable has a value of NULL with a type of string.

9.4. System Variables

Starting from MySQL 4.0.3, we provide better access to a lot of system and connection variables. Many variables can be changed dynamically while the server is running. This allows you to modify server operation without having to stop and restart it.

The mysqld server maintains two kinds of variables. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections.

When the server starts, it initializes all global variables to their default values. These defaults may be changed by options specified in option files or on the command line. After the server starts, those global variables that are dynamic can be changed by connecting to the server and issuing a SET GLOBAL var_name statement. To change a global variable, you must have the SUPER privilege.

The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For those session variables that are dynamic, the client can change them by issuing a SET SESSION var_name statement. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.

A change to a global variable is visible to any client that accesses that global variable. However, it affects the corresponding session variable that is initialized from the global variable only for clients that connect after the change. It does not affect the session variable for any client that is currently connected (not even that of the client that issues the SET GLOBAL statement).

Global or session variables may be set or retrieved using several syntax forms. The following examples use sort_buffer_size as a sample variable name.

To set the value of a GLOBAL variable, use one of the following syntaxes:

```
mysql> SET GLOBAL sort_buffer_size=value;
mysql> SET @@global.sort_buffer_size=value;
```

To set the value of a SESSION variable, use one of the following syntaxes:

```
mysql> SET SESSION sort_buffer_size=value;
mysql> SET @@session.sort_buffer_size=value;
```

```
mysql> SET sort_buffer_size=value;
```

LOCAL is a synonym for SESSION.

If you don't specify GLOBAL, SESSION, or LOCAL when setting a variable, SESSION is the default. See Section 13.5.3, "SET Syntax".

To retrieve the value of a GLOBAL variable, use one of the following statements:

```
mysql> SELECT @@global.sort_buffer_size;
mysql> SHOW GLOBAL VARIABLES like 'sort_buffer_size';
```

To retrieve the value of a SESSION variable, use one of the following statements:

```
mysql> SELECT @@sort_buffer_size;
mysql> SELECT @@session.sort_buffer_size;
mysql> SHOW SESSION VARIABLES like 'sort_buffer_size';
```

Here, too, LOCAL is a synonym for SESSION.

When you retrieve a variable with SELECT @@var_name (that is, you do not specify global., session., or local., MySQL returns the SESSION value if it exists and the GLOBAL value otherwise.

For SHOW VARIABLES, if you do not specify GLOBAL, SESSION, or LOCAL, MySQL returns the SESSION value.

The reason for requiring the GLOBAL keyword when setting GLOBAL-only variables but not when retrieving them is to prevent problems in the future. If we remove a SESSION variable with the same name as a GLOBAL variable, a client with the SUPER privilege might accidentally change the GLOBAL variable rather than just the SESSION variable for its own connection. If we add a SESSION variable with the same name as a GLOBAL variable, a client that intends to change the GLOBAL variable might find only its own SESSION variable changed.

Further information about system startup options and system variables can be found in Section 5.3.1, "mysqld Command-Line Options" and Section 5.3.3, "Server System Variables". A list of the variables that can be set at runtime is given in Section 5.3.3.1, "Dynamic System Variables".

9.4.1. Structured System Variables

Structured system variables are supported beginning with MySQL 4.1.1. A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.

- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

Currently, MySQL supports one structured variable type. It specifies parameters that govern the operation of key caches. A key cache structured variable has these components:

- key_buffer_size

- key_cache_block_size

- key_cache_division_limit

- key_cache_age_threshold

The purpose of this section is to describe the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in Section 7.4.6, "The `MyISAM` Key Cache".

To refer to a component of a structured variable instance, you can use a compound name in `in-stance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

The naming rules for structured variable instances and components are as follows:

* For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.

* The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.

* If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but `` `hot-cache` `` is.

* `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@global.`*`var_name`* for referring to non-structured system variables.

At the moment, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules assume greater significance if some other type of structured variable is created in the future.

With one exception, it is allowable to refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, do this:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with such an option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \
         --extra_cache.key_buffer_size=128K \
         --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written

`--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \
          --hot_cache.key_buffer_size=2M \
          --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

9.5. Comment Syntax

The MySQL server supports three comment styles:

- From a '#' character to the end of the line.

- From a '-- ' sequence to the end of the line. This style is supported as of MySQL 3.23.3. Note that the '-- ' (double-dash) comment style requires the second dash to be followed by at least one space (or by a control character such as a newline). This syntax differs slightly from standard SQL comment syntax, as discussed in Section 1.8.5.7, "'--' as the Start of a Comment".

- From a `/*` sequence to the following '`*/`' sequence. The closing sequence need not be on the same line, so this syntax allows a comment to extend over multiple lines.

The following example demonstrates all three comment styles:

```
mysql> SELECT 1+1;     # This comment continues to the end of line
mysql> SELECT 1+1;     -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+
/*
this is a
multiple-line comment
*/
1;
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (For example, it does this to determine statement boundaries within a multiple-statement input line.) However, there are some limitations on the way that `mysql` parses `/* ... */` comments:

- A semicolon within the comment is taken to indicate the end of the current SQL statement and anything following it to indicate the beginning of the next statement. This problem was fixed in MySQL 4.0.13.

- A single quote, double quote, or backtick character is taken to indicate the beginning of a quoted string or identifier, even within a comment. If the quote is not matched by a second quote within the comment, the parser doesn't realize the comment has ended. If you are running `mysql` interactively, you can tell that it has gotten confused like this because the prompt changes from `mysql>` to `'>`, `">`, or `` `> ``. This problem was fixed in MySQL 4.1.1.

- An exclamation point used with this style of comment delimiter (such as `/*! ... */`) marks portions of SQL statements for conditional execution. For more information and examples, see Section 1.8.4, "MySQL Extensions to Standard SQL".

For affected versions of MySQL, these limitations apply both when you run `mysql` interactively and when you put commands in a file and use `mysql` in batch mode to process the file with `mysql < *file_name*`.

9.6. Treatment of Reserved Words in MySQL

A common problem stems from trying to use an identifier such as a table or column name that is the name of a built-in MySQL data type or function, such as `TIMESTAMP` or `GROUP`. You're allowed to do this (for example, `ABS` is allowed as a column name). However, by default, no whitespace is allowed in function invocations between the function name and the following '(' character. This requirement allows a function call to be distinguished from a reference to a column name.

A side effect of this behavior is that omitting a space in some contexts causes an identifier to be interpreted as a function name. For example, this statement is legal:

```
mysql> CREATE TABLE abs (val INT);
```

But omitting the space after `abs` causes a syntax error because the statement then appears to invoke the `ABS()` function:

```
mysql> CREATE TABLE abs(val INT);
```

If the server SQL mode includes the `IGNORE_SPACE` mode value, the server allows function invocations to have whitespace between a function name and the following '(' character. This causes function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in Section 9.2, "Database, Table, Index, Column, and Alias Names". The server SQL mode is controlled as described in Section 5.3.2, "The Server SQL Mode".

A word that follows a period in a qualified name must be an identifier, so it is not necessary to quote it, even if it is a reserved word.

The words in the following table are explicitly reserved in MySQL. Most of them are forbidden by standard SQL as column and/or table names (for example, `GROUP`). A few are reserved because MySQL needs them and (currently) uses a `yacc` parser. A reserved word can be used as an identifier if you quote it.

MySQL allows some keywords to be used as unquoted identifiers because many people previously used them. Examples are those in the following list:

- `ACTION`

- `BIT`

- `DATE`

- `ENUM`

- `NO`

- `TEXT`

- `TIME`

- `TIMESTAMP`

Chapter 10. Character Set Support

Improved support for character set handling was added to MySQL in Version 4.1. The features described here are as implemented in MySQL 4.1.1. (MySQL 4.1.0 has some but not all of these features, and some of them are implemented differently.)

This chapter discusses the following topics:

- What are character sets and collations?

- The multiple-level default system

- New syntax in MySQL 4.1

- Affected functions and operations

- Unicode support

- The meaning of each individual character set and collation

Character set support currently is included in the `MyISAM`, `MEMORY (HEAP)`, and (as of MySQL 4.1.2) `InnoDB` storage engines. The `ISAM` storage engine does not include character set support; there are no plans to change this, because `ISAM` is deprecated.

10.1. Character Sets and Collations in General

A **character set** is a set of symbols and encodings. A **collation** is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: 'A', 'B', 'a', 'b'. We give each letter a number: 'A' = 0, 'B' = 1, 'a' = 2, 'b' = 3. The letter 'A' is a symbol, the number 0 is the **encoding** for 'A', and the combination of all four letters and their encodings is a **character set**.

Suppose that we want to compare two string values, 'A' and 'B'. The simplest way to do this is to look at the encodings: 0 for 'A' and 1 for 'B'. Because 0 is less than 1, we say 'A' is less than 'B'. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): "compare the encodings." We call this simplest of all possible collations a **binary** collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters 'a' and 'b' as equivalent to 'A' and 'B'; (2) then compare the encodings. We call this a **case-insensitive** collation. It's a little more complex than a binary collation.

In real life, most character sets have many characters: not just 'A' and 'B' but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules: not just case insensitivity but also accent insensitivity (an "accent" is a mark attached to a character as in German 'Ö') and multiple-character mappings (such as the rule that 'Ö' = 'OE' in one of the two German collations).

MySQL 4.1 can do these things for you:

- Store strings using a variety of character sets

- Compare strings using a variety of collations

- Mix strings with different character sets or collations in the same server, the same database, or even the same table

- Allow specification of character set and collation at any level

In these respects, not only is MySQL 4.1 far more flexible than MySQL 4.0, it also is far ahead of other DBMSs. However, to use the new features effectively, you need to learn what character sets and collations are available, how to change their defaults, and what the various string operators do with them.

10.2. Character Sets and Collations in MySQL

The MySQL server can support multiple character sets. To list the available character sets, use the `SHOW CHARACTER SET` statement:

```
mysql> SHOW CHARACTER SET;
+----------+-----------------------------+----------------------+---------+
| Charset  | Description                 | Default collation    | Maxlen  |
+----------+-----------------------------+----------------------+---------+
| big5     | Big5 Traditional Chinese    | big5_chinese_ci      |    2    |
| dec8     | DEC West European           | dec8_swedish_ci      |    1    |
| cp850    | DOS West European           | cp850_general_ci     |    1    |
| hp8      | HP West European            | hp8_english_ci       |    1    |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci     |    1    |
| latin1   | cp1252 West European        | latin1_swedish_ci    |    1    |
| latin2   | ISO 8859-2 Central European | latin2_general_ci    |    1    |
| swe7     | 7bit Swedish                | swe7_swedish_ci      |    1    |
| ascii    | US ASCII                    | ascii_general_ci     |    1    |
| ujis     | EUC-JP Japanese             | ujis_japanese_ci     |    3    |
| sjis     | Shift-JIS Japanese          | sjis_japanese_ci     |    2    |
| hebrew   | ISO 8859-8 Hebrew           | hebrew_general_ci    |    1    |
| tis620   | TIS620 Thai                 | tis620_thai_ci       |    1    |
| euckr    | EUC-KR Korean               | euckr_korean_ci      |    2    |
...
```

Any given character set always has at least one collation. It may have several collations.

To list the collations for a character set, use the `SHOW COLLATION` statement. For example, to see the collations for the `latin1` ("cp1252 West European") character set, use this statement to find those collation names that begin with `latin1`:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+-------------------+---------+-----+---------+----------+---------+
| Collation         | Charset | Id  | Default | Compiled | Sortlen |
+-------------------+---------+-----+---------+----------+---------+
| latin1_german1_ci | latin1  |  5  |         |          |    0    |
| latin1_swedish_ci | latin1  |  8  | Yes     | Yes      |    1    |
| latin1_danish_ci  | latin1  | 15  |         |          |    0    |
| latin1_german2_ci | latin1  | 31  |         | Yes      |    2    |
| latin1_bin        | latin1  | 47  |         | Yes      |    1    |
| latin1_general_ci | latin1  | 48  |         |          |    0    |
| latin1_general_cs | latin1  | 49  |         |          |    0    |
| latin1_spanish_ci | latin1  | 94  |         |          |    0    |
+-------------------+---------+-----+---------+----------+---------+
```

The `latin1` collations have the following meanings:

Collation	Meaning
latin1_bin	Binary according to latin1 encoding
latin1_danish_ci	Danish/Norwegian

`latin1_general_ci`	Multilingual
`latin1_general_cs`	Multilingual, case sensitive
`latin1_german1_ci`	German DIN-1
`latin1_german2_ci`	German DIN-2
`latin1_spanish_ci`	Modern Spanish
`latin1_swedish_ci`	Swedish/Finnish

Collations have these general characteristics:

- Two different character sets cannot have the same collation.

- Each character set has one collation that is the *default collation*. For example, the default collation for `latin1` is `latin1_swedish_ci`.

- There is a convention for collation names: They start with the name of the character set with which they are associated, they usually include a language name, and they end with `_ci` (case insensitive), `_cs` (case sensitive), or `_bin` (binary).

10.3. Determining the Default Character Set and Collation

There are default settings for character sets and collations at four levels: server, database, table, and connection. The following description may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

10.3.1. Server Character Set and Collation

The MySQL Server has a server character set and a server collation, neither of which which may be null.

MySQL determines the server character set and server collation as follows:

- According to the option settings in effect when the server starts

- According to the values set at runtime

At the server level, the decision is simple. The server character set and collation depend initially on the options that you use when you start `mysqld`. You can use `--default-character-set` for the character set, and along with it you can add `--default-collation` for the collation. If you don't specify a character set, that is the same as saying `--default-character-set=latin1`. If you specify only a character set (for example, `latin1`) but not a collation, that is the same as saying `--default-charset=latin1 --default-collation=latin1_swedish_ci` because `latin1_swedish_ci` is the default collation for `latin1`. Therefore, the following three commands all have the same effect:

```
shell> mysqld
shell> mysqld --default-character-set=latin1
shell> mysqld --default-character-set=latin1 \
          --default-collation=latin1_swedish_ci
```

One way to change the settings is by recompiling. If you want to change the default server character set and collation when building from sources, use: `--with-charset` and `--with-collation` as arguments for `configure`. For example:

```
shell> ./configure --with-charset=latin1
```

Or:

```
shell> ./configure --with-charset=latin1 \
          --with-collation=latin1_german1_ci
```

Both `mysqld` and `configure` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The current server character set and collation are available as the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

10.3.2. Database Character Set and Collation

Every database has a database character set and a database collation, which may not be null. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]
```

Example:

```
CREATE DATABASE db_name
    DEFAULT CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation thus:

- If both `CHARACTER SET X` and `COLLATE Y` were specified, then character set X and collation Y.

- If `CHARACTER SET X` was specified without `COLLATE`, then character set X and its default collation.

- Otherwise, the server character set and server collation.

MySQL's `CREATE DATABASE ... DEFAULT CHARACTER SET ...` syntax is analogous to the standard SQL `CREATE SCHEMA ... CHARACTER SET ...` syntax. Because of this, it is possible to create databases with different character sets and collations on the same MySQL server.

The database character set and collation are used as default values if the table character set and collation are not specified in `CREATE TABLE` statements. They have no other purpose.

The character set and collation for the default database are available as the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level variables, `character_set_server` and `collation_server`.

10.3.3. Table Character Set and Collation

Every table has a table character set and a table collation, which may not be null. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
    [DEFAULT CHARACTER SET charset_name [COLLATE collation_name]]

ALTER TABLE tbl_name
    [DEFAULT CHARACTER SET charset_name] [COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 ( ... )
    DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation thus:

- If both `CHARACTER SET` *X* and `COLLATE` *Y* were specified, then character set *X* and collation *Y*.

- If `CHARACTER SET` *X* was specified without `COLLATE`, then character set *X* and its default collation.

- Otherwise, the database character set and collation.

The table character set and collation are used as default values if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

10.3.4. Column Character Set and Collation

Every "character" column (that is, a column of type `CHAR`, `VARCHAR`, or `TEXT`) has a column character set and a column collation, which may not be null. Column definition syntax has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
    [CHARACTER SET charset_name [COLLATE collation_name]]
```

Example:

```
CREATE TABLE Table1
(
    column1 VARCHAR(5) CHARACTER SET latin1 COLLATE latin1_german1_ci
);
```

MySQL chooses the column character set and collation thus:

- If both `CHARACTER SET` *X* and `COLLATE` *Y* were specified, then character set *X* and collation *Y*.

- If `CHARACTER SET` *X* was specified without `COLLATE`, then character set X and its default collation.

- Otherwise, the table character set and collation.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

10.3.5. Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

Example 1: Table + Column Definition

```
CREATE TABLE t1
(
    c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that's straightforward. Notice that there's no problem storing a `latin1` column in a `latin2` table.

Example 2: Table + Column Definition

```
CREATE TABLE t1
(
    c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

Example 3: Table + Column Definition

```
CREATE TABLE t1
(
    c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL looks up to the table level for inspiration in determining the column character set and collation. So, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

Example 4: Database + Table + Column Definition

```
CREATE DATABASE d1
    DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
(
    c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL looks up to the database level for inspiration. (The database's settings become the table's settings, and thereafter become the column's setting.) So, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

10.3.6. Connection Character Sets and Collations

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The server character set and collation are available as the values of the `character_set_server` and `collation_server` variables.

- The character set and collation of the default database are available as the values of the `character_set_database` and `collation_database` variables.

Additional character set and collation variables are involved in handling traffic for the connection between a client and the server. Every client has connection-related character set and collation variables.

Consider what a "connection" is: It's what you make when you connect to the server. The client sends SQL statements, such as queries, over the connection to the server. The server sends responses, such as result sets, over the connection back to the client. This leads to several questions about character set and collation handling for client connections, each of which can be answered in terms of system variables:

- What character set is the query in when it leaves the client?

  The server takes the `character_set_client` variable to be the character set in which queries are sent by the client.

- What character set should the server translate a query to after receiving it?

  For this, `character_set_connection` and `collation_connection` are used by the server. It converts queries sent by the client from `character_set_client` to `character_set_connection` (except for string literals that have an introducer such as `_latin1` or `_utf8`). `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, it does not matter because columns have a higher collation precedence.

- What character set should the server translate to before shipping result sets or error messages back to the client?

  The `character_set_results` variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, and result metadata such as column names.

You can fine-tune the settings for these variables, or you can depend on the defaults (in which case, you can skip this section).

There are two statements that affect the connection character sets:

```
SET NAMES 'charset_name'
SET CHARACTER SET charset_name
```

`SET NAMES` indicates what is in the SQL statements that the client sends. Thus, `SET NAMES 'cp1251'` tells the server "future incoming messages from this client are in character set `cp1251`." It also specifies the character set for results that the server sends back to the client. (For example, it indicates what character set column values are if you use a `SELECT` statement.)

A `SET NAMES 'x'` statement is equivalent to these three statements:

```
mysql> SET character_set_client = x;
mysql> SET character_set_results = x;
mysql> SET character_set_connection = x;
```

Setting `character_set_connection` to x also sets `collation_connection` to the default collation for x.

`SET CHARACTER SET` is similar but sets the connection character set and collation to be those of the default database. A `SET CHARACTER SET x` statement is equivalent to these three statements:

```
mysql> SET character_set_client = x;
mysql> SET character_set_results = x;
mysql> SET collation_connection = @@collation_database;
```

When a client connects, it sends to the server the name of the character set that it wants to use. The server sets the `character_set_client`, `character_set_results`, and `character_set_connection` variables to that character set. (In effect, the server performs a `SET NAMES` operation using the character set.)

With the `mysql` client, it is not necessary to execute `SET NAMES` every time you start up if you want to use a character set different from the default. You can add the `--default-character-set` option setting to your `mysql` statement line, or in your option file. For example, the following option file setting changes the three character set variables set to `koi8r` each time you run `mysql`:

```
[mysql]
default-character-set=koi8r
```

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET latin1`, then just before sending results back, the server converts the `latin2` values to `latin1`. Conversion may be lossy if there are characters that are not in both character sets.

If you do not want the server to perform any conversion, set `character_set_results` to `NULL`:

```
mysql> SET character_set_results = NULL;
```

10.3.7. Character String Literal Character Set and Collation

Every character string literal has a character set and a collation, which may not be null.

A character string literal may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT 'string';
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

For the simple statement `SELECT 'string'`, the string has the character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

The `_charset_name` expression is formally called an *introducer*. It tells the parser, "the string that is about to follow is in character set X." Because this has confused people in the past, we emphasize that an introducer does not cause any conversion, it is strictly a signal that does not change the string's value. An introducer is also legal before standard hex literal and numeric hex literal notation (`x'literal'` and `0xnnnn`), and before ? (parameter substitution when using prepared state-

ments within a programming language interface).

Examples:

```
SELECT _latin1 x'AABBCC';
SELECT _latin1 0xAABBCC;
SELECT _latin1 ?;
```

MySQL determines a literal's character set and collation thus:

- If both _*X* and COLLATE *Y* were specified, then character set *X* and collation *Y*

- If _*X* is specified but COLLATE is not specified, then character set *X* and its default collation

- Otherwise, the character set and collation given by the character_set_connection and collation_connection system variables

Examples:

- A string with latin1 character set and latin1_german1_ci collation:

  ```
  SELECT _latin1'Müller' COLLATE latin1_german1_ci;
  ```

- A string with latin1 character set and its default collation (that is, latin1_swedish_ci):

  ```
  SELECT _latin1'Müller';
  ```

- A string with the connection default character set and collation:

  ```
  SELECT 'Müller';
  ```

Character set introducers and the COLLATE clause are implemented according to standard SQL specifications.

10.3.8. Using COLLATE in SQL Statements

With the COLLATE clause, you can override whatever the default collation is for a comparison. COLLATE may be used in various parts of SQL statements. Here are some examples:

- With ORDER BY:

  ```
  SELECT k
  FROM t1
  ORDER BY k COLLATE latin1_german2_ci;
  ```

- With AS:

  ```
  SELECT k COLLATE latin1_german2_ci AS k1
  FROM t1
  ORDER BY k1;
  ```

- With GROUP BY:

  ```
  SELECT k
  FROM t1
  GROUP BY k COLLATE latin1_german2_ci;
  ```

- With aggregate functions:

```
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With `DISTINCT`:

```
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

- With `WHERE`:

```
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

- With `HAVING`:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

10.3.9. `COLLATE` Clause Precedence

The `COLLATE` clause has high precedence (higher than `||`), so the following two expressions are equivalent:

```
x || y COLLATE z
x || (y COLLATE z)
```

10.3.10. `BINARY` Operator

The `BINARY` operator is a shorthand for a `COLLATE` clause. `BINARY 'x'` is equivalent to `'x'` `COLLATE y`, where `y` is the name of the binary collation for the character set of `'x'`. Every character set has a binary collation. For example, the binary collation for the `latin1` character set is `latin1_bin`, so if the column `a` is of character set `latin1`, the following two statements have the same effect:

```
SELECT * FROM t1 ORDER BY BINARY a;
SELECT * FROM t1 ORDER BY a COLLATE latin1_bin;
```

10.3.11. Some Special Cases Where the Collation Determination Is Tricky

In the great majority of queries, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is "the column collation of column `x`":

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, when multiple operands are involved, there can be ambiguity. For example:

```
SELECT x FROM T WHERE x = 'Y';
```

Should this query use the collation of the column `x`, or of the string literal `'Y'`?

Standard SQL resolves such questions using what used to be called "coercibility" rules. The essence is: Because `x` and `'Y'` both have collations, whose collation takes precedence? It's complex, but the following rules take care of most situations:

• An explicit `COLLATE` clause has a coercibility of 0. (Not coercible at all.)

• A concatenation of two strings with different collations has a coercibility of 1.

• A column's collation has a coercibility of 2.

• A "system constant" (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.

• A literal's collation has a coercibility of 4.

• `NULL` or an expression that is derived from `NULL` has a coercibility of 5.

The preceding coercibility values are current as of MySQL 4.1.11 and 5.0.3. See the note later in this section for additional version-related information.

Those rules resolve ambiguities thus:

• Use the collation with the lowest coercibility value.

• If both sides have the same coercibility, then it is an error if the collations aren't the same.

Examples:

`column1 = 'A'`	Use collation of `column1`
`column1 = 'A' COLLATE x`	Use collation of `'A'`
`column1 COLLATE x = 'A' COLLATE y`	Error

The `COERCIBILITY()` function can be used to determine the coercibility of a string expression:

```
mysql> SELECT COERCIBILITY('A' COLLATE latin1_swedish_ci);
        -> 0
mysql> SELECT COERCIBILITY(VERSION());
        -> 3
mysql> SELECT COERCIBILITY('A');
        -> 4
```

See Section 12.9.3, "Information Functions".

Before MySQL 4.1.11 and 5.0.3, there is no system constant or ignorable coercibility. Functions such as `USER()` have a coercibility of 2 rather than 3, and literals have a coercibility of 3 rather than 4.

10.3.12. Collations Must Be for the Right Character Set

Recall that each character set has one or more collations, and each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1251: COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

In some cases, expressions that worked before MySQL 4.1 fail in early versions of MySQL 4.1 if you do not take character set and collation into account. For example, before 4.1, this statement works as is:

```
mysql> SELECT SUBSTRING_INDEX(USER(),'@',1);
+------------------------------+
| SUBSTRING_INDEX(USER(),'@',1) |
+------------------------------+
| root                         |
+------------------------------+
```

The statement also works as is in MySQL 4.1 as of 4.1.8: In MySQL 4.1, usernames are stored using the `utf8` character set (see Section 10.6, "UTF8 for Metadata"). The literal string `'@'` has the server character set (`latin1` by default). Although the character sets are different, MySQL can coerce the `latin1` string to the character set (and collation) of `USER()` without data loss. It does so, performs the substring operation, and returns a result that has a character set of `utf8`.

However, in versions of MySQL 4.1 before 4.1.8, the statement fails:

```
mysql> SELECT SUBSTRING_INDEX(USER(),'@',1);
ERROR 1267 (HY000): Illegal mix of collations
(utf8_general_ci,IMPLICIT) and (latin1_swedish_ci,COERCIBLE)
for operation 'substr_index'
```

This happens because the automatic character set conversion of `'@'` does not occur and the string operands have different character sets (and thus different collations):

```
mysql> SELECT COLLATION(USER()), COLLATION('@');
+-------------------+-------------------+
| COLLATION(USER()) | COLLATION('@')    |
+-------------------+-------------------+
| utf8_general_ci   | latin1_swedish_ci |
+-------------------+-------------------+
```

One way to deal with this is to upgrade to MySQL 4.1.8 or later. If that is not possible, you can tell MySQL to interpret the literal string as `utf8`:

```
mysql> SELECT SUBSTRING_INDEX(USER(),_utf8'@',1);
+------------------------------------+
| SUBSTRING_INDEX(USER(),_utf8'@',1) |
+------------------------------------+
| root                               |
+------------------------------------+
```

Another way is to change the connection character set and collation to `utf8`. You can do that with `SET NAMES 'utf8'` or by setting the `character_set_connection` and `collation_connection` system variables directly.

10.3.13. An Example of the Effect of Collation

Suppose that column `X` in table `T` has these `latin1` column values:

```
Muffler
Müller
MX Systems
MySQL
```

And suppose that the column values are retrieved using the following statement:

```
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The resulting order of the values for different collations is shown in this table:

latin1_swedish_ci	latin1_german1_ci	latin1_german2_ci
Muffler	Muffler	Müller
MX Systems	Müller	Muffler
Müller	MX Systems	MX Systems
MySQL	MySQL	MySQL

The table is an example that shows what the effect would be if we used different collations in an ORDER BY clause. The character that causes the different sort orders in this example is the U with two dots over it, which the Germans call U-umlaut, but we'll call it U-diaeresis.

- The first column shows the result of the SELECT using the Swedish/Finnish collating rule, which says that U-diaeresis sorts with Y.

- The second column shows the result of the SELECT using the German DIN-1 rule, which says that U-diaeresis sorts with U.

- The third column shows the result of the SELECT using the German DIN-2 rule, which says that U-diaeresis sorts with UE.

Three different collations, three different results. That's what MySQL is here to handle. By using the appropriate collation, you can choose the sort order you want.

10.4. Operations Affected by Character Set Support

This section describes operations that take character set information into account as of MySQL 4.1.

10.4.1. Result Strings

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, UPPER(X) returns a string whose character string and collation are the same as that of X. The same applies for IN-STR(), LCASE(), LOWER(), LTRIM(), MID(), REPEAT(), REPLACE(), REVERSE(), RIGHT(), RPAD(), RTRIM(), SOUNDEX(), SUBSTRING(), TRIM(), UCASE(), and UP-PER(). (Also note: The REPLACE() function, unlike all other functions, ignores the collation of the string input and performs a case-insensitive comparison every time.)

For operations that combine multiple string inputs and return a single string output, the "aggregation rules" of standard SQL apply:

- If an explicit COLLATE X occurs, then use X

- If an explicit COLLATE X and COLLATE Y occur, then error

- Otherwise, if all collations are X, then use X

- Otherwise, the result has no collation

For example, with CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END, the resultant collation is X. The same applies for CASE, UNION, ||, CONCAT(), ELT(), GREATEST(), IF(), and LEAST().

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the character_set_connection and collation_connection system variables. This applies for CAST(), CHAR(), CONV(), FORMAT(), HEX(), and SPACE().

10.4.2. CONVERT()

CONVERT() provides a way to convert data between different character sets. The syntax is:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8table (utf8column)
    SELECT CONVERT(latin1field USING utf8) FROM latin1table;
```

CONVERT(... USING ...) is implemented according to the standard SQL specification.

In TRADITIONAL SQL mode, if you convert a "zero" date string to a date, CONVERT() returns NULL. MySQL 5.0.4 and above also produces a warning.

10.4.3. CAST()

You may also use CAST() to convert a string to a different character set. The syntax is:

```
CAST(character_string AS character_data_type CHARACTER SET charset_name)
```

Example:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8);
```

If you use CAST() without specifying CHARACTER SET, the resulting character set and collation are defined by the character_set_connection and collation_connection system variables. If you use CAST() with CHARACTER SET X, then the resulting character set and collation are X and the default collation of X.

You may not use a COLLATE clause inside a CAST(), but you may use it outside. That is, CAST(... COLLATE ...) is illegal, but CAST(...) COLLATE ... is legal.

Example:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

In TRADITIONAL SQL mode, if you convert a "zero" date string to a date, CAST() returns NULL.
MySQL 5.0.4 and above also produces a warning.

10.4.4. SHOW Statements

Several SHOW statements are new or modified in MySQL 4.1 to provide additional character set information. SHOW CHARACTER SET, SHOW COLLATION, and SHOW CREATE DATABASE are new. SHOW CREATE TABLE and SHOW COLUMNS are modified.

The SHOW CHARACTER SET command shows all available character sets. It takes an optional LIKE clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+---------+-----------------------------+-------------------+--------+
```

See Section 13.5.4.1, "SHOW CHARACTER SET Syntax".

The output from SHOW COLLATION includes all available character sets. It takes an optional LIKE clause that indicates which collation names to match. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+-------------------+---------+----+---------+----------+---------+
| Collation         | Charset | Id | Default | Compiled | Sortlen |
+-------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1  |  5 |         |          |       0 |
| latin1_swedish_ci | latin1  |  8 | Yes     | Yes      |       0 |
| latin1_danish_ci  | latin1  | 15 |         |          |       0 |
| latin1_german2_ci | latin1  | 31 |         | Yes      |       2 |
| latin1_bin        | latin1  | 47 |         | Yes      |       0 |
| latin1_general_ci | latin1  | 48 |         |          |       0 |
| latin1_general_cs | latin1  | 49 |         |          |       0 |
| latin1_spanish_ci | latin1  | 94 |         |          |       0 |
+-------------------+---------+----+---------+----------+---------+
```

See Section 13.5.4.2, "SHOW COLLATION Syntax".

SHOW CREATE DATABASE displays the CREATE DATABASE statement that creates a given database. The result includes all database options. DEFAULT CHARACTER SET and COLLATE are supported. All database options are stored in a text file named db.opt that can be found in the database directory.

```
mysql> SHOW CREATE DATABASE a\G
*************************** 1. row ***************************
       Database: a
Create Database: CREATE DATABASE `a`
                 /*!40100 DEFAULT CHARACTER SET macce */
```

See Section 13.5.4.4, "SHOW CREATE DATABASE Syntax".

SHOW CREATE TABLE is similar, but displays the CREATE TABLE statement to create a given table. The column definitions indicate any character set specifications, and the table options include character set information.

See Section 13.5.4.5, "SHOW CREATE TABLE Syntax".

The SHOW COLUMNS statement displays the collations of a table's columns when invoked as SHOW

`FULL COLUMNS`. Columns with `CHAR`, `VARCHAR`, or `TEXT` data types have non-`NULL` collations. Numeric and other non-character types have `NULL` collations. For example:

```
mysql> SHOW FULL COLUMNS FROM t;
+-------+---------+------------+------+-----+---------+-------+
| Field | Type    | Collation  | Null | Key | Default | Extra |
+-------+---------+------------+------+-----+---------+-------+
| a     | char(1) | latin1_bin | YES  |     | NULL    |       |
| b     | int(11) | NULL       | YES  |     | NULL    |       |
+-------+---------+------------+------+-----+---------+-------+
```

The character set is not part of the display. (The character set name is implied by the collation name.)

See Section 13.5.4.3, "`SHOW COLUMNS` Syntax".

10.5. Unicode Support

As of MySQL version 4.1, there are two new character sets for storing Unicode data:

- `ucs2`, the UCS-2 Unicode character set.

- `utf8`, the UTF8 encoding of the Unicode character set.

In UCS-2 (binary Unicode representation), every character is represented by a two-byte Unicode code with the most significant byte first. For example: "LATIN CAPITAL LETTER A" has the code 0x0041 and it's stored as a two-byte sequence: 0x00 0x41. "CYRILLIC SMALL LETTER YERU" (Unicode 0x044B) is stored as a two-byte sequence: 0x04 0x4B. For Unicode characters and their codes, please refer to the Unicode Home Page [http://www.unicode.org/].

A temporary restriction is that UCS-2 cannot yet be used as a client character set. That means that `SET NAMES 'ucs2'` does not work.

The UTF8 character set (transform Unicode representation) is an alternative way to store Unicode data. It is implemented according to RFC 3629. The idea of the UTF8 character set is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.

- Most European and Middle East script letters fit into a two-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.

- Korean, Chinese, and Japanese ideographs use three-byte sequences.

RFC 3629 describes encoding sequences that take from one to four bytes. Currently, MySQL UTF8 support does not include four-byte sequences. (An older standard for UTF8 encoding is given by RFC 2279, which describes UTF8 sequences that take from one to six bytes. RFC 3629 renders RFC 2279 obsolete; for this reason, sequences with five and six bytes are no longer used.)

Tip: To save space with UTF8, use `VARCHAR` instead of `CHAR`. Otherwise, MySQL has to reserve 30 bytes for a `CHAR(10) CHARACTER SET utf8` column, because that's the maximum possible length.

10.6. UTF8 for Metadata

The metadata is the data about the data. Anything that describes the database, as opposed to being the contents of the database, is metadata. Thus column names, database names, usernames, version

names, and most of the string results from SHOW are metadata.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, SHOW wouldn't work properly because different rows in the same column would be in different character sets.

- Metadata must include all characters in all languages. Otherwise, users wouldn't be able to name columns and tables in their own languages.

In order to satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF8. This does not cause any disruption if you never use accented characters. But if you do, you should be aware that metadata is in UTF8.

This means that the USER(), CURRENT_USER(), DATABASE(), and VERSION() functions have the UTF8 character set by default, as do synonyms such as SESSION_USER() and SYS-TEM_USER().

The server sets the character_set_system system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+----------------------+-------+
| Variable_name        | Value |
+----------------------+-------+
| character_set_system | utf8  |
+----------------------+-------+
```

Storage of metadata using Unicode does *not* mean that the headers of columns and the results of DESCRIBE functions are in the character_set_system character set by default. When you say SELECT column1 FROM t, the name column1 itself is returned from the server to the client in the character set as determined by the SET NAMES statement. More specifically, the character set used is determined by the value of the character_set_results system variable. If this variable is set to NULL, no conversion is performed and the server returns metadata using its original character set (the set indicated by character_set_system).

If you want the server to pass metadata results back in a non-UTF8 character set, then use SET NAMES to force the server to perform character set conversion (see Section 10.3.6, "Connection Character Sets and Collations"), or else set the client to do the conversion. It is always more efficient to set the client to do the conversion, but this option is not available for many clients until late in the MySQL 4.x product cycle.

If you are just using, for example, the USER() function for comparison or assignment within a single statement, don't worry. MySQL does some automatic conversion for you.

```
SELECT * FROM Table1 WHERE USER() = latin1_column;
```

This works because the contents of latin1_column are automatically converted to UTF8 before the comparison.

```
INSERT INTO Table1 (latin1_column) SELECT USER();
```

This works because the contents of USER() are automatically converted to latin1 before the assignment. Automatic conversion is not fully implemented yet, but should work correctly in a later version.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a "subset" of Unicode. Since it is a well-known principle that "what applies to a superset can apply to a subset," we believe that a collation for Unicode can apply for comparisons with non-Unicode strings.

10.7. Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(n) UNICODE);
CREATE TABLE t1 (f1 CHAR(n) CHARACTER SET ucs2);
```

10.8. New Character Set Configuration File Format

In MySQL 4.1, character set configuration is stored in XML files, one file per character set. In previous versions, this information was stored in `.conf` files.

10.9. National Character Set

Before MySQL 4.1, `NCHAR` and `CHAR` were synonymous. ANSI defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL 4.1 and up uses `utf8` as that predefined character set. For example, these column type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use `N'literal'` to create a string in the national character set. These two statements are equivalent:

```
SELECT N'some text';
SELECT _utf8'some text';
```

10.10. Upgrading Character Sets from MySQL 4.0

What about upgrading from older versions of MySQL? MySQL 4.1 is almost upward compatible with MySQL 4.0 and earlier for the simple reason that almost all the features are new, so there's nothing in earlier versions to conflict with. However, there are some differences and a few things to be aware of.

It is important to note that the "MySQL 4.0 character set" contains both character set and collation information in one single entity. Beginning in MySQL 4.1, character sets and collations are separate entities. Though each collation corresponds to a particular character set, the two are not bundled together.

There is a special treatment of national character sets in MySQL 4.1. `NCHAR` is not the same as `CHAR`, and `N'...'` literals are not the same as `'...'` literals.

Finally, there is a different file format for storing information about character sets and collations.

Make sure that you have reinstalled the /share/mysql/charsets/ directory containing the new configuration files.

If you want to start mysqld from a 4.1.x distribution with data created by MySQL 4.0, you should start the server with the same character set and collation. In this case, you won't need to reindex your data.

There are two ways to do so:

```
shell> ./configure --with-charset=... --with-collation=...
shell> ./mysqld --default-character-set=... --default-collation=...
```

If you used mysqld with, for example, the MySQL 4.0 danish character set, you should use the latin1 character set and the latin1_danish_ci collation:

```
shell> ./configure --with-charset=latin1 \
        --with-collation=latin1_danish_ci
shell> ./mysqld --default-character-set=latin1 \
        --default-collation=latin1_danish_ci
```

Use the table shown in Section 10.10.1, "4.0 Character Sets and Corresponding 4.1 Character Set/Collation Pairs" to find old 4.0 character set names and their 4.1 character set/collation pair equivalents.

If you have non-latin1 data stored in a 4.0 latin1 table and want to convert the table column definitions to reflect the actual character set of the data, use the instructions in Section 10.10.2, "Converting 4.0 Character Columns to 4.1 Format".

10.10.1. 4.0 Character Sets and Corresponding 4.1 Character Set/Collation Pairs

ID	4.0 Character Set	4.1 Character Set	4.1 Collation
1	big5	big5	big5_chinese_ci
2	czech	latin2	latin2_czech_ci
3	dec8	dec8	dec8_swedish_ci
4	dos	cp850	cp850_general_ci
5	german1	latin1	latin1_german1_ci
6	hp8	hp8	hp8_english_ci
7	koi8_ru	koi8r	koi8r_general_ci
8	latin1	latin1	latin1_swedish_ci
9	latin2	latin2	latin2_general_ci
10	swe7	swe7	swe7_swedish_ci
11	usa7	ascii	ascii_general_ci
12	ujis	ujis	ujis_japanese_ci
13	sjis	sjis	sjis_japanese_ci
14	cp1251	cp1251	cp1251_bulgarian_ci
15	danish	latin1	latin1_danish_ci
16	hebrew	hebrew	hebrew_general_ci
17	win1251	(removed)	(removed)
18	tis620	tis620	tis620_thai_ci
19	euc_kr	euckr	euckr_korean_ci
20	estonia	latin7	latin7_estonian_ci

21	hungarian	latin2	latin2_hungarian_ci
22	koi8_ukr	koi8u	koi8u_ukrainian_ci
23	win1251ukr	cp1251	cp1251_ukrainian_ci
24	gb2312	gb2312	gb2312_chinese_ci
25	greek	greek	greek_general_ci
26	win1250	cp1250	cp1250_general_ci
27	croat	latin2	latin2_croatian_ci
28	gbk	gbk	gbk_chinese_ci
29	cp1257	cp1257	cp1257_lithuanian_ci
30	latin5	latin5	latin5_turkish_ci
31	latin1_de	latin1	latin1_german2_ci

10.10.2. Converting 4.0 Character Columns to 4.1 Format

Normally, the server runs using the latin1 character set by default. If you have been storing column data that actually is in some other character set that the 4.1 server supports directly, you can convert the column. However, you should avoid trying to convert directly from latin1 to the "real" character set. This may result in data loss. Instead, convert the column to a binary column type, and then from the binary type to a non-binary type with the desired character set. Conversion to and from binary involves no attempt at character value conversion and preserves your data intact. For example, suppose that you have a 4.0 table with three columns that are used to store values represented in latin1, latin2, and utf8:

```
CREATE TABLE t
(
    latin1_col CHAR(50),
    latin2_col CHAR(100),
    utf8_col CHAR(150)
);
```

For MySQL 4.1, you want to convert this table to leave latin1_col alone but change the latin2_col and utf8_col columns to have character sets of latin2 and utf8. Before upgrading to 4.1, back up your table, then convert the columns as follows:

```
ALTER TABLE t MODIFY latin2_col BINARY(100);
ALTER TABLE t MODIFY utf8_col BINARY(150);
```

Then, after upgrading to 4.1, complete the conversion by issuing these statements:

```
ALTER TABLE t MODIFY latin2_col CHAR(100) CHARACTER SET latin2;
ALTER TABLE t MODIFY utf8_col CHAR(150) CHARACTER SET utf8;
```

The first two statements "remove" the character set information from the latin2_col and utf8_col columns. The second two statements assign the proper character sets to the two columns.

If you like, you can combine the to-binary conversions and from-binary conversions into single statements. In MySQL 4.0, do this:

```
ALTER TABLE t
    MODIFY latin2_col BINARY(100),
    MODIFY utf8_col BINARY(150);
```

After upgrading to 4.1, do this:

```
ALTER TABLE t
    MODIFY latin2_col CHAR(100) CHARACTER SET latin2,
    MODIFY utf8_col CHAR(150) CHARACTER SET utf8;
```

If you can ensure that the tables will not otherwise be modified before you perform the character set conversion, you can issue all of the ALTER TABLE statements after upgrading to MySQL 4.1.

If you specified attributes when creating a column initially, you should also specify them when altering the table with ALTER TABLE. For example, if you specified NOT NULL and an explicit DEFAULT value, you should also provide them in the ALTER TABLE statement. Otherwise, the resulting column definition will not include those attributes.

10.11. Character Sets and Collations That MySQL Supports

Here is an annotated list of character sets and collations that MySQL supports. Because options and installation settings differ, some sites might not have all items listed, and some sites might have items not listed.

MySQL supports 70+ collations for 30+ character sets. The character sets and their default collations are displayed by the SHOW CHARACTER SET statement. (The output actually includes another column that is not shown so that the example fits better on the page.)

```
mysql> SHOW CHARACTER SET;
+----------+-----------------------------+---------------------+
| Charset  | Description                 | Default collation   |
+----------+-----------------------------+---------------------+
| big5     | Big5 Traditional Chinese    | big5_chinese_ci     |
| dec8     | DEC West European           | dec8_swedish_ci     |
| cp850    | DOS West European           | cp850_general_ci    |
| hp8      | HP West European            | hp8_english_ci      |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    |
| latin1   | cp1252 West European        | latin1_swedish_ci   |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   |
| swe7     | 7bit Swedish                | swe7_swedish_ci     |
| ascii    | US ASCII                    | ascii_general_ci    |
| ujis     | EUC-JP Japanese             | ujis_japanese_ci    |
| sjis     | Shift-JIS Japanese          | sjis_japanese_ci    |
| hebrew   | ISO 8859-8 Hebrew           | hebrew_general_ci   |
| tis620   | TIS620 Thai                 | tis620_thai_ci      |
| euckr    | EUC-KR Korean               | euckr_korean_ci     |
| koi8u    | KOI8-U Ukrainian            | koi8u_general_ci    |
| gb2312   | GB2312 Simplified Chinese    | gb2312_chinese_ci   |
| greek    | ISO 8859-7 Greek            | greek_general_ci    |
| cp1250   | Windows Central European    | cp1250_general_ci   |
| gbk      | GBK Simplified Chinese       | gbk_chinese_ci      |
| latin5   | ISO 8859-9 Turkish          | latin5_turkish_ci   |
| armscii8 | ARMSCII-8 Armenian          | armscii8_general_ci |
| utf8     | UTF-8 Unicode               | utf8_general_ci     |
| ucs2     | UCS-2 Unicode               | ucs2_general_ci     |
| cp866    | DOS Russian                 | cp866_general_ci    |
| keybcs2  | DOS Kamenicky Czech-Slovak  | keybcs2_general_ci  |
| macce    | Mac Central European        | macce_general_ci    |
| macroman | Mac West European           | macroman_general_ci |
| cp852    | DOS Central European        | cp852_general_ci    |
| latin7   | ISO 8859-13 Baltic          | latin7_general_ci   |
| cp1251   | Windows Cyrillic            | cp1251_general_ci   |
| cp1256   | Windows Arabic              | cp1256_general_ci   |
| cp1257   | Windows Baltic              | cp1257_general_ci   |
| binary   | Binary pseudo charset       | binary              |
| geostd8  | GEOSTD8 Georgian            | geostd8_general_ci  |
| cp932    | SJIS for Windows Japanese   | cp932_japanese_ci   |
```

```
| eucjpms  | UJIS for Windows Japanese  | eucjpms_japanese_ci |
+----------+----------------------------+---------------------+
```

10.11.1. Unicode Character Sets

MySQL has two Unicode character sets. You can store texts in about 650 languages using these character sets. We have added several collations for these two new sets, with more to come.

- `ucs2` (UCS-2 Unicode) collations:

  - `ucs2_bin`

  - `ucs2_czech_ci`

  - `ucs2_danish_ci`

  - `ucs2_estonian_ci`

  - `ucs2_general_ci` (default)

  - `ucs2_icelandic_ci`

  - `ucs2_latvian_ci`

  - `ucs2_lithuanian_ci`

  - `ucs2_persian_ci`

  - `ucs2_polish_ci`

  - `ucs2_roman_ci`

  - `ucs2_romanian_ci`

  - `ucs2_slovak_ci`

  - `ucs2_slovenian_ci`

  - `ucs2_spanish2_ci`

  - `ucs2_spanish_ci`

  - `ucs2_swedish_ci`

  - `ucs2_turkish_ci`

  - `ucs2_unicode_ci`

Note that there's a limitation in MySQL 4.1 that results in two characters not being correctly handled when a user tries to change their case using `LOWER()` or `UPPER()`:

- LATIN SMALL LETTER DOTLESS i

- LATIN CAPITAL LETTER I WITH DOT ABOVE

Here are two workarounds for MySQL 4.1:

1. Use UCS2 if you have Turkish data.

2. Use these function calls:

   ```
   CONVERT(LOWER(CONVERT(col USING ucs2)) USING utf8)
   ```

- `utf8` (UTF-8 Unicode) collations:

  - `utf8_bin`

  - `utf8_czech_ci`

  - `utf8_danish_ci`

  - `utf8_estonian_ci`

  - `utf8_general_ci` (default)

  - `utf8_icelandic_ci`

  - `utf8_latvian_ci`

  - `utf8_lithuanian_ci`

  - `utf8_persian_ci`

  - `utf8_polish_ci`

  - `utf8_roman_ci`

  - `utf8_romanian_ci`

  - `utf8_slovak_ci`

  - `utf8_slovenian_ci`

  - `utf8_spanish2_ci`

  - `utf8_spanish_ci`

  - `utf8_swedish_ci`

  - `utf8_turkish_ci`

  - `utf8_unicode_ci`

The `utf8_unicode_ci` collation is implemented according to the Unicode Collation Algorithm (UCA) described at http://www.unicode.org/reports/tr10/. The collation uses the version-4.0.0 UCA weight keys: http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt. (The following discussion uses `utf8_unicode_ci`, but it is also true for `ucs2_unicode_ci`.)

Currently, the `utf8_unicode_ci` collation has only partial support for the Unicode Collation Algorithm. Some characters are not supported yet. Also, combining marks are not fully supported. This affects primarily Vietnamese and some minority languages in Russia such as Udmurt, Tatar, Bashkir, and Mari.

The most significant feature in `utf8_unicode_ci` is that it supports expansions, that is, when one character compares equal to several characters. For example, in German and some other languages 'ß' is equal to 'ss'.

`utf8_general_ci` is a legacy collation that does not support expansions. It can only compare characters one to one. This means that comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`).

For example, the following equalities hold in both `utf8_general_ci` and `utf8_unicode_ci`:

```
Ä = A
Ö = O
Ü = U
```

A difference between the collations is that this is true for `utf8_general_ci`:

ß = s

Whereas this is true for `utf8_unicode_ci`:

ß = ss

Language-specific collations for the `utf8` character set are implemented only if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German and French, so there is no need to create special `utf8` collations for these two languages.

`utf8_general_ci` is fine for both German and French, too, with an exception that 'ß' is equal to 's', not to 'ss'. If that is acceptable for your application, use `utf8_general_ci` because it is faster. Otherwise, use `utf8_unicode_ci` because it is "smarter."

`utf8_swedish_ci`, like other `utf8` language-specific collations, is derived from `utf8_unicode_ci` with additional language rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

Ü = Y < Ö

The `utf8_spanish_ci` and `utf8_spanish2_ci` collations correspond to modern Spanish and traditional Spanish, respectively. In both collations, 'ñ' (n-tilde) is a separate letter between 'n' and 'o'. In addition, for traditional Spanish, 'ch' is a separate letter between 'c' and d, and 'll' is a separate letter between 'l' and 'm'

10.11.2. West European Character Sets

West European Character Sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:

  - `ascii_bin`

  - `ascii_general_ci` (default)

- `cp850` (DOS West European) collations:

  - `cp850_bin`

  - `cp850_general_ci` (default)

- `dec8` (DEC West European) collations:

  - `dec8_bin`

  - `dec8_swedish_ci` (default)

- `hp8` (HP West European) collations:

  - `hp8_bin`

  - `hp8_english_ci` (default)

- `latin1` (cp1252 West European) collations:

  - `latin1_bin`

  - `latin1_danish_ci`

  - `latin1_general_ci`

  - `latin1_general_cs`

  - `latin1_german1_ci`

  - `latin1_german2_ci`

  - `latin1_spanish_ci`

  - `latin1_swedish_ci` (default)

  The `latin1` is the default character set. The `latin1_swedish_ci` collation is the default that probably is used by the majority of MySQL customers. It is constantly stated that this is based on the Swedish/Finnish collation rules, but you can find Swedes and Finns who disagree with that statement.

  The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for Deutsches Institut für Normung (that is, the German answer to ANSI). DIN-1 is called the dictionary collation and DIN-2 is called the phone-book collation.

  - `latin1_german1_ci` (dictionary) rules:

    ```
    Ä = A
    Ö = O
    Ü = U
    ß = s
    ```

  - `latin1_german2_ci` (phone-book) rules:

    ```
    Ä = AE
    Ö = OE
    Ü = UE
    ß = ss
    ```

  In the `latin1_spanish_ci` collation, 'ñ' (n-tilde) is a separate letter between 'n' and 'o'.

- `macroman` (Mac West European) collations:

  - `macroman_bin`

  - `macroman_general_ci` (default)

- `swe7` (7bit Swedish) collations:

  - `swe7_bin`

  - `swe7_swedish_ci` (default)

10.11.3. Central European Character Sets

We have some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, and Poland.

- `cp1250` (Windows Central European) collations:

  - `cp1250_bin`

  - `cp1250_croatian_ci`

  - `cp1250_czech_cs`

  - `cp1250_general_ci` (default)

- `cp852` (DOS Central European) collations:

  - `cp852_bin`

  - `cp852_general_ci` (default)

- `keybcs2` (DOS Kamenicky Czech-Slovak) collations:

  - `keybcs2_bin`

  - `keybcs2_general_ci` (default)

- `latin2` (ISO 8859-2 Central European) collations:

  - `latin2_bin`

  - `latin2_croatian_ci`

  - `latin2_czech_cs`

  - `latin2_general_ci` (default)

  - `latin2_hungarian_ci`

- `macce` (Mac Central European) collations:

  - `macce_bin`

  - `macce_general_ci` (default)

10.11.4. South European and Middle East Character Sets

- `armscii8` (ARMSCII-8 Armenian) collations:

  - `armscii8_bin`

  - `armscii8_general_ci` (default)

- `cp1256` (Windows Arabic) collations:

  - `cp1256_bin`

  - `cp1256_general_ci` (default)

- `geostd8` (GEOSTD8 Georgian) collations:

  - `geostd8_bin`

  - `geostd8_general_ci` (default)

- greek (ISO 8859-7 Greek) collations:

  - greek_bin

  - greek_general_ci (default)

- hebrew (ISO 8859-8 Hebrew) collations:

  - hebrew_bin

  - hebrew_general_ci (default)

- latin5 (ISO 8859-9 Turkish) collations:

  - latin5_bin

  - latin5_turkish_ci (default)

10.11.5. Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages. There are two Baltic character sets currently supported:

- cp1257 (Windows Baltic) collations:

  - cp1257_bin

  - cp1257_general_ci (default)

  - cp1257_lithuanian_ci

- latin7 (ISO 8859-13 Baltic) collations:

  - latin7_bin

  - latin7_estonian_cs

  - latin7_general_ci (default)

  - latin7_general_cs

10.11.6. Cyrillic Character Sets

Here are the Cyrillic character sets and collations for use with Belarusian, Bulgarian, Russian, and Ukrainian languages.

- cp1251 (Windows Cyrillic) collations:

  - cp1251_bin

  - cp1251_bulgarian_ci

  - cp1251_general_ci (default)

  - cp1251_general_cs

  - cp1251_ukrainian_ci

- cp866 (DOS Russian) collations:

- `cp866_bin`

- `cp866_general_ci` (default)

- `koi8r` (KOI8-R Relcom Russian) collations:

  - `koi8r_bin`

  - `koi8r_general_ci` (default)

- `koi8u` (KOI8-U Ukrainian) collations:

  - `koi8u_bin`

  - `koi8u_general_ci` (default)

10.11.7. Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters.

- `big5` (Big5 Traditional Chinese) collations:

  - `big5_bin`

  - `big5_chinese_ci` (default)

- `cp932` (SJIS for Windows Japanese) collations:

  - `cp932_bin`

  - `cp932_japanese_ci` (default)

- `eucjpms` (UJIS for Windows Japanese) collations:

  - `eucjpms_bin`

  - `eucjpms_japanese_ci` (default)

- `euckr` (EUC-KR Korean) collations:

  - `euckr_bin`

  - `euckr_korean_ci` (default)

- `gb2312` (GB2312 Simplified Chinese) collations:

  - `gb2312_bin`

  - `gb2312_chinese_ci` (default)

- `gbk` (GBK Simplified Chinese) collations:

  - `gbk_bin`

  - `gbk_chinese_ci` (default)

- `sjis` (Shift-JIS Japanese) collations:

  - `sjis_bin`

- `sjis_japanese_ci` (default)

- `tis620` (TIS620 Thai) collations:

  - `tis620_bin`

  - `tis620_thai_ci` (default)

- `ujis` (EUC-JP Japanese) collations:

  - `ujis_bin`

  - `ujis_japanese_ci` (default)

10.11.7.1. The `cp932` Character Set

Why is `cp932` needed?

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See http://www.iana.org/assignments/character-sets.)

However, the meaning of "SHIFT JIS" as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various venders.

For example, "SHIFT JIS" used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is `Microsoft Windows Codepage : 932` or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected — IBM extended characters, and IBM extended characters.

Since MySQL 4.1, many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.

- Character sets are converted via Unicode (`ucs2`).

- The `sjis` character set does not support the conversion of these extension characters.

- There are several conversion rules from so-called "SHIFT JIS" to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems. It is available as of MySQL 4.1.12 and 5.0.3.

Before MySQL 4.1, it was safe to use any version of "SHIFT JIS" in conjunction with the `sjis` character set. However, because MySQL supports character set conversion beginning with 4.1, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

How does `cp932` differ from `sjis`?

The `cp932` character set differs from `sjis` in the following ways:

- `cp932` supports NEC special characters, NEC selected — IBM extended characters, and IBM selected characters.

- Some `cp932` characters have two different code points, both of which convert to the same Uni-

code code point. So, when converting from Unicode back to `cp932`, one of the code points must be selected. For this "round trip conversion," the rule recommended by Microsoft is used. (See http://support.microsoft.com/kb/170559/EN-US/.)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.

- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.

- If the character is in both IBM selected characters and NEC selected — IBM extended characters, use the code point of IBM extended characters.

Information about the Unicode values of `cp932` characters is given in the table shown at http://www.microsoft.com/globaldev/reference/dbcs/932.htm. For `cp932` table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (`ucs2`) encoding. For table entries with an underlined two-digit value appears, there is a range of `cp932` character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the `cp932` characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters:

  ```
  http://www.microsoft.com/globaldev/reference/dbcs/932/932_87.htm
  ```

- NEC selected — IBM extended characters:

  ```
  http://www.microsoft.com/globaldev/reference/dbcs/932/932_ED.htm
  http://www.microsoft.com/globaldev/reference/dbcs/932/932_EE.htm
  ```

- IBM selected characters:

  ```
  http://www.microsoft.com/globaldev/reference/dbcs/932/932_FA.htm
  http://www.microsoft.com/globaldev/reference/dbcs/932/932_FB.htm
  http://www.microsoft.com/globaldev/reference/dbcs/932/932_FC.htm
  ```

- Starting from version 5.0.3, `cp932` supports conversion of user-defined characters in combination with `eucjpms`, and solves the problems with `sjis`/`ujis` conversion. For details, please refer to http://www.opengroup.or.jp/jvc/cde/sjis-euc-e.html.

- For some characters, conversion to and from `ucs2` is different for `sjis` and `cp932`. The following tables illustrate these differences.

  Conversion to `ucs2`:

`sjis`/`cp932` Value	`sjis` # `ucs2` Conversion	`cp932` # `ucs2` Conversion
5C	005C	005C
7E	007E	007E
815C	2015	2015
815F	005C	FF3C
8160	301C	FF5E
8161	2016	2225
817C	2212	FF0D

8191	00A2	FFE0
8192	00A3	FFE1
81CA	00AC	FFE2

Conversion from `ucs2`:

ucs2 value	**ucs2 # `sjis` Conversion**	**ucs2 # `cp932` Conversion**
005C	815F	5C
007E	7E	7E
00A2	8191	3F
00A3	8192	3F
00AC	81CA	3F

FFE0	3F	8191
FFE1	3F	8192
FFE2	3F	81CA

Chapter 11. Column Types

MySQL supports a number of column types in several categories: numeric types, date and time types, and string (character) types. This chapter first gives an overview of these column types, and then provides a more detailed description of the properties of the types in each category, and a summary of the column type storage requirements. The overview is intentionally brief. The more detailed descriptions should be consulted for additional information about particular column types, such as the allowable formats in which you can specify values.

MySQL versions 4.1 and up support extensions for handing spatial data. Information about spatial types is provided in Chapter 17, *Spatial Extensions in MySQL.*

Several of the column type descriptions use these conventions:

- *M*

    Indicates the maximum display width. The maximum legal display width is 255.

- *D*

    Applies to floating-point and fixed-point types and indicates the number of digits following the decimal point. The maximum possible value is 30, but should be no greater than *M*-2.

- Square brackets ('`[`' and '`]`') indicate parts of type specifiers that are optional.

11.1. Column Type Overview

11.1.1. Overview of Numeric Types

A summary of the numeric column types follows. For additional information, see Section 11.2, "Numeric Types". Column storage requirements are given in Section 11.5, "Column Type Storage Requirements".

M indicates the maximum display width. The maximum legal display width is 255. Display width is unrelated to the storage size or range of values a type can contain, as described in Section 11.2, "Numeric Types".

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

Warning: You should be aware that when you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned. See Section 12.8, "Cast Functions and Operators".

- `BIT[(M)]`

    A bit-field type. *M* indicates the number of bits per value, from 1 to 64. The default is 1 if *M* is omitted.

    This data type was added in MySQL 5.0.3 for `MyISAM`, and extended in 5.0.5 to `MEMORY`, `InnoDB`, and `BDB`. Before 5.0.3, `BIT` is a synonym for `TINYINT(1)`.

- `TINYINT[(M)] [UNSIGNED] [ZEROFILL]`

A very small integer. The signed range is `-128` to `127`. The unsigned range is `0` to `255`.

- `BOOL`, `BOOLEAN`

These are synonyms for `TINYINT(1)`. The `BOOLEAN` synonym was added in MySQL 4.1.0. A value of zero is considered false. Non-zero values are considered true.

In the future, full boolean type handling will be introduced in accordance with standard SQL.

- `SMALLINT[(M)] [UNSIGNED] [ZEROFILL]`

A small integer. The signed range is `-32768` to `32767`. The unsigned range is `0` to `65535`.

- `MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]`

A medium-size integer. The signed range is `-8388608` to `8388607`. The unsigned range is `0` to `16777215`.

- `INT[(M)] [UNSIGNED] [ZEROFILL]`

A normal-size integer. The signed range is `-2147483648` to `2147483647`. The unsigned range is `0` to `4294967295`.

- `INTEGER[(M)] [UNSIGNED] [ZEROFILL]`

This is a synonym for `INT`.

- `BIGINT[(M)] [UNSIGNED] [ZEROFILL]`

A large integer. The signed range is `-9223372036854775808` to `9223372036854775807`. The unsigned range is `0` to `18446744073709551615`.

Some things you should be aware of with respect to `BIGINT` columns:

- All arithmetic is done using signed `BIGINT` or `DOUBLE` values, so you shouldn't use unsigned big integers larger than `9223372036854775807` (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a `BIGINT` value to a `DOUBLE`.

  MySQL 4.0 can handle `BIGINT` in the following cases:

  - When using integers to store big unsigned values in a `BIGINT` column.

  - In `MIN(col_name)` or `MAX(col_name)`, where `col_name` refers to a `BIGINT` column.

  - When using operators (`+`, `-`, `*`, and so on) where both operands are integers.

- You can always store an exact integer value in a `BIGINT` column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.

- The `-`, `+`, and `*` operators use `BIGINT` arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than `9223372036854775807`.

- `FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]`

A small (single-precision) floating-point number. Allowable values are `-3.402823466E+38` to `-1.175494351E-38`, `0`, and `1.175494351E-38` to `3.402823466E+38`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of decimal digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits allowed by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

If `UNSIGNED` is specified, negative values are disallowed.

Using `FLOAT` might give you some unexpected problems because all calculations in MySQL are done with double precision. See Section A.5.7, "Solving Problems with No Matching Rows".

- `DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]`

  A normal-size (double-precision) floating-point number. Allowable values are –1.7976931348623157E+308 to –2.2250738585072014E–308, 0, and 2.2250738585072014E–308 to 1.7976931348623157E+308. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

  M is the total number of decimal digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits allowed by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

  If `UNSIGNED` is specified, negative values are disallowed.

- `FLOAT(p) [UNSIGNED] [ZEROFILL]`

  A floating-point number. *p* represents the precision in bits, but MySQL uses this value only to determine whether to give the resulting column a data type of `FLOAT` or `DOUBLE`. If *p* is from 0 to 24, the data type becomes `FLOAT` with no *M* or *D* values. If *p* is from 25 to 53, the data type becomes `DOUBLE` with no *M* or *D* values. The range of the resulting column is the same as for the single-precision `FLOAT` or double-precision `DOUBLE` data types described earlier in this section.

  As of MySQL 3.23, this data type holds true floating-point values. In earlier MySQL versions, `FLOAT(p)` always has two decimals.

  `FLOAT(p)` syntax is provided for ODBC compatibility.

- `DOUBLE PRECISION[(M,D)] [UNSIGNED] [ZEROFILL]` , `REAL[(M,D)] [UNSIGNED] [ZEROFILL]`

  These are synonyms for `DOUBLE`. Exception: If the server SQL mode includes the `REAL_AS_FLOAT` option, `REAL` is a synonym for `FLOAT` rather than `DOUBLE`.

- `DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]`

  For MySQL 5.0.3 and above:

  A packed "exact" fixed-point number. *M* is the total number of decimal digits (the precision) and *D* is the number of decimal digits after the decimal point (the scale). The decimal point and (for negative numbers) the '–' sign are not counted in *M*. If *D* is 0, values have no decimal point or fractional part. The maximum number of digits (*M*) for `DECIMAL` is 64. The maximum number of supported decimals (*D*) is 30. If *D* is omitted, the default is 0. If *M* is omitted, the default is 10.

  If `UNSIGNED` is specified, negative values are disallowed.

  All basic calculations (`+`, `-`, `*`, `/`) with `DECIMAL` columns are done with a precision of 64 decimal digits.

  Before MySQL 5.0.3:

  An unpacked fixed-point number. Behaves like a `CHAR` column; "unpacked" means the number is stored as a string, using one character for each digit of the value. *M* is the total number of decimal digits and *D* is the number of decimal digits after the decimal point. The decimal point

and (for negative numbers) the '-' sign are not counted in M, although space for them is reserved. If D is 0, values have no decimal point or fractional part. The maximum range of DECIMAL values is the same as for DOUBLE, but the actual range for a given DECIMAL column may be constrained by the choice of M and D. If D is omitted, the default is 0. If M is omitted, the default is 10.

If UNSIGNED is specified, negative values are disallowed.

Before MySQL 3.23:

As just described, with the exception that the M value must be large enough to include the space needed for the sign and the decimal point characters.

- DEC[(*M*[,*D*])] [UNSIGNED] [ZEROFILL] , NUMERIC[(*M*[,*D*])] [UNSIGNED]
  [ZEROFILL] , FIXED[(*M*[,*D*])] [UNSIGNED] [ZEROFILL]

  These are synonyms for DECIMAL. The FIXED synonym was added in MySQL 4.1.0 for compatibility with other servers.

11.1.2. Overview of Date and Time Types

A summary of the temporal column types follows. For additional information, see Section 11.3, "Date and Time Types". Column storage requirements are given in Section 11.5, "Column Type Storage Requirements".

- DATE

  A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays DATE values in 'YYYY-MM-DD' format, but allows you to assign values to DATE columns using either strings or numbers.

- DATETIME

  A date and time combination. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'. MySQL displays DATETIME values in 'YYYY-MM-DD HH:MM:SS' format, but allows you to assign values to DATETIME columns using either strings or numbers.

- TIMESTAMP[(*M*)]

  A timestamp. The range is '1970-01-01 00:00:00' to partway through the year 2037.

  A TIMESTAMP column is useful for recording the date and time of an INSERT or UPDATE operation. The first TIMESTAMP column in a table is automatically set to the date and time of the most recent operation if you don't assign it a value yourself. You can also set any TIMESTAMP column to the current date and time by assigning it a NULL value.

  From MySQL 4.1 on, TIMESTAMP is returned as a string with the format 'YYYY-MM-DD HH:MM:SS'. Display widths (used as described in the following paragraphs) are no longer supported; the display width is fixed at 19 characters. If you want to obtain the value as a number, you should add +0 to the timestamp column.

  In MySQL 4.0 and earlier, TIMESTAMP values are displayed in YYYYMMDDHHMMSS, YYMMDDHHMMSS, YYYYMMDD, or YYMMDD format, depending on whether M is 14 (or missing), 12, 8, or 6, but allows you to assign values to TIMESTAMP columns using either strings or numbers. The M argument affects only how a TIMESTAMP column is displayed, not storage. Its values always are stored using four bytes each. From MySQL 4.0.12, the --new option can be used to make the server behave as in MySQL 4.1.

  Note that TIMESTAMP(*M*) columns where M is 8 or 14 are reported to be numbers, whereas other TIMESTAMP(*M*) columns are reported to be strings. This is just to ensure that you can re-

liably dump and restore the table with these types.

Note: The behaviour of TIMESTAMP columns changed considerably in MySQL 4.1. For complete information on the differences with regard to this column type in MySQL 4.1 and later versions (as opposed to MySQL 4.0 and earlier versions), be sure to see Section 11.3.1.1, "TIMESTAMP Properties Prior to MySQL 4.1" and Section 11.3.1.2, "TIMESTAMP Properties as of MySQL 4.1".

• TIME

  A time. The range is '-838:59:59' to '838:59:59'. MySQL displays TIME values in 'HH:MM:SS' format, but allows you to assign values to TIME columns using either strings or numbers.

• YEAR[(2|4)]

  A year in two-digit or four-digit format. The default is four-digit format. In four-digit format, the allowable values are 1901 to 2155, and 0000. In two-digit format, the allowable values are 70 to 69, representing years from 1970 to 2069. MySQL displays YEAR values in YYYY format, but allows you to assign values to YEAR columns using either strings or numbers. The YEAR type is unavailable prior to MySQL 3.22.

11.1.3. Overview of String Types

A summary of the string column types follows. For additional information, see Section 11.4, "String Types". Column storage requirements are given in Section 11.5, "Column Type Storage Requirements".

In some cases, MySQL may change a string column to a type different from that given in a CREATE TABLE or ALTER TABLE statement. See Section 13.1.5.1, "Silent Column Specification Changes".

As of MySQL 4.1, several changes affect string data types:

• Column definitions for many string data types can include a CHARACTER SET attribute to specify the character set and, optionally, a collation. (CHARSET is a synonym for CHARACTER SET.) These attributes apply to CHAR, VARCHAR, the TEXT types, ENUM, and SET. For example:

```
CREATE TABLE t
(
    c1 CHAR(20) CHARACTER SET utf8,
    c2 CHAR(20) CHARACTER SET latin1 COLLATE latin1_bin
);
```

  This table definition creates a column named c1 that has a character set of utf8 with the default collation for that character set, and a column named c2 that has a character set of latin1 and the binary collation for the character set. The binary collation is not case sensitive.

• MySQL 4.1, MySQL interprets length specifications in character column definitions in character units. Earlier versions interpret lengths in byte units.

• For CHAR, VARCHAR, and the TEXT types, the BINARY attribute causes the column to be assigned the binary collation of the column character set. For earlier versions, BINARY causes CHAR and VARCHAR to be treated as binary strings and is disallowed for the TEXT types.

• Character column sorting and comparison are based on the character set assigned to the column. For earalier versions, sorting and comparison are based on the collation of the server character set. For CHAR and VARCHAR columns, you can declare the column with the BINARY attribute to cause sorting and comparison to use the underlying character code values rather then a lexical

ordering.

For more details about character set support in MySQL 4.1 and up, see Chapter 10, *Character Set Support*.

- `[NATIONAL] CHAR(M) [BINARY | ASCII | UNICODE]`

  A fixed-length string that is always right-padded with spaces to the specified length when stored. *M* represents the column length. The range of *M* is 0 to 255 characters (1 to 255 prior to MySQL 3.23).

  Note: Trailing spaces are removed when `CHAR` values are retrieved.

  From MySQL 4.1.0 to 5.0.2, a `CHAR` column with a length specification greater than 255 is converted to the smallest `TEXT` type that can hold values of the given length. For example, `CHAR(500)` is converted to `TEXT`, and `CHAR(200000)` is converted to `MEDIUMTEXT`. This is a compatibility feature. However, this conversion causes the column to become a variable-length column, and also affects trailing-space removal.

  `CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use the default character set. This is the default in MySQL.

  As of MySQL 4.1.2, the `BINARY` attribute is shorthand for specifying the binary collation of the column character set. Sorting and comparison is based on numeric character values. Before 4.1.2, `BINARY` attribute causes the column to be treated as a binary string. Sorting and comparison is based on numeric byte values.

  From MySQL 4.1.0 on, column type `CHAR BYTE` is an alias for `CHAR BINARY`. This is a compatibility feature.

  From MySQL 4.1.0 on, the `ASCII` attribute can be specified for `CHAR`. It assigns the `latin1` character set.

  From MySQL 4.1.1 on, the `UNICODE` attribute can be specified for `CHAR`. It assigns the `ucs2` character set.

  MySQL allows you to create a column of type `CHAR(0)`. This is mainly useful when you have to be compliant with some old applications that depend on the existence of a column but that do not actually use the value. This is also quite nice when you need a column that can take only two values: A `CHAR(0)` column that is not defined as `NOT NULL` occupies only one bit and can take only the values `NULL` and `' '` (the empty string).

- `CHAR`

  This is a synonym for `CHAR(1)`.

- `[NATIONAL] VARCHAR(M) [BINARY]`

  A variable-length string. *M* represents the maximum column length. The range of *M* is 1 to 255 before MySQL 4.0.2, 0 to 255 as of MySQL 4.0.2, and 0 to 65,535 as of MySQL 5.0.3. (The maximum actual length of a `VARCHAR` in MySQL 5.0 is determined by the maximum row size and the character set you use. The maximum effective length is 65,532 bytes.)

  Note: Before 5.0.3, trailing spaces were removed when `VARCHAR` values were stored, which differs from the standard SQL specification.

  From MySQL 4.1.0 to 5.0.2, a `VARCHAR` column with a length specification greater than 255 is converted to the smallest `TEXT` type that can hold values of the given length. For example, `VARCHAR(500)` is converted to `TEXT`, and `VARCHAR(200000)` is converted to `MEDIUM-TEXT`. This is a compatibility feature. However, this conversion affects trailing-space removal.

VARCHAR is shorthand for CHARACTER VARYING.

As of MySQL 4.1.2, the BINARY attribute is shorthand for specifying the binary collation of the column character set. Sorting and comparison is based on numeric character values. Before 4.1.2, BINARY attribute causes the column to be treated as a binary string. Sorting and comparison is based on numeric byte values.

Starting from MySQL 5.0.3, VARCHAR is stored with a one-byte or two-byte length prefix + data. The length prefix is two bytes if the VARCHAR column is declared with a length greater than 255.

- BINARY(*M*)

The BINARY type is similar to the CHAR type, but stores binary byte strings rather than non-binary character strings.

This type was added in MySQL 4.1.2.

- VARBINARY(*M*)

The VARBINARY type is similar to the VARCHAR type, but stores binary byte strings rather than non-binary character strings.

This type was added in MySQL 4.1.2.

- TINYBLOB

A BLOB column with a maximum length of 255 (2^8 – 1) bytes.

- TINYTEXT

A TEXT column with a maximum length of 255 (2^8 – 1) characters.

- BLOB[(*M*)]

A BLOB column with a maximum length of 65,535 (2^{16} – 1) bytes.

Beginning with MySQL 4.1, an optional length *M* can be given. MySQL will create the column as the smallest BLOB type largest enough to hold values *M* bytes long.

- TEXT[(*M*)]

A TEXT column with a maximum length of 65,535 (2^{16} – 1) characters.

Beginning with MySQL 4.1, an optional length *M* can be given. MySQL will create the column as the smallest TEXT type largest enough to hold values *M* characters long.

- MEDIUMBLOB

A BLOB column with a maximum length of 16,777,215 (2^{24} – 1) bytes.

- MEDIUMTEXT

A TEXT column with a maximum length of 16,777,215 (2^{24} – 1) characters.

- LONGBLOB

A BLOB column with a maximum length of 4,294,967,295 or 4GB (2^{32} – 1) bytes. Up to MySQL 3.23, the client/server protocol and MyISAM tables had a limit of 16MB per communication packet / table row. From MySQL 4.0, the maximum allowed length of LONGBLOB columns depends on the configured maximum packet size in the client/server protocol and available memory.

- `LONGTEXT`

  A `TEXT` column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) characters. Up to MySQL 3.23, the client/server protocol and `MyISAM` tables had a limit of 16MB per communication packet / table row. From MySQL 4.0, the maximum allowed length of `LONGTEXT` columns depends on the configured maximum packet size in the client/server protocol and available memory.

- `ENUM('value1','value2',...)`

  An enumeration. A string object that can have only one value, chosen from the list of values `'value1'`, `'value2'`, `...`, `NULL` or the special `''` error value. An `ENUM` column can have a maximum of 65,535 distinct values. `ENUM` values are represented internally as integers.

- `SET('value1','value2',...)`

  A set. A string object that can have zero or more values, each of which must be chosen from the list of values `'value1'`, `'value2'`, `...` A `SET` column can have a maximum of 64 members. `SET` values are represented internally as integers.

11.2. Numeric Types

MySQL supports all of the standard SQL numeric data types. These types include the exact numeric data types (`INTEGER`, `SMALLINT`, `DECIMAL`, and `NUMERIC`), as well as the approximate numeric data types (`FLOAT`, `REAL`, and `DOUBLE PRECISION`). The keyword `INT` is a synonym for `IN-TEGER`, and the keyword `DEC` is a synonym for `DECIMAL`.

As of MySQL 5.0.3, a `BIT` data type is available for storing bit-field values. (Before 5.0.3, MySQL interprets `BIT` as `TINYINT(1)`.) In MySQL 5.0.3, `BIT` is supported only for `MyISAM`. MySQL 5.0.5 extends `BIT` support to `MEMORY`, `InnoDB`, and `BDB`.

As an extension to the SQL standard, MySQL also supports the integer types `TINYINT`, `MEDI-UMINT`, and `BIGINT`. The following table shows the required storage and range for each of the integer types.

Type	Bytes	Minimum Value (Signed/Unsigned)	Maximum Value (Signed/Unsigned)
`TINYINT`	1	-128	127
		0	255
`SMALLINT`	2	-32768	32767
		0	65535
`MEDIUMINT`	3	-8388608	8388607
		0	16777215
`INT`	4	-2147483648	2147483647
		0	4294967295
`BIGINT`	8	-9223372036854775808	9223372036854775807
		0	18446744073709551615

Another extension is supported by MySQL for optionally specifying the display width of an integer value in parentheses following the base keyword for the type (for example, `INT(4)`). This optional display width specification is used to left-pad the display of values having a width less than the width specified for the column.

The display width does not constrain the range of values that can be stored in the column, nor the number of digits that are displayed for values having a width exceeding that specified for the

column.

When used in conjunction with the optional extension attribute `ZEROFILL`, the default padding of spaces is replaced with zeros. For example, for a column declared as `INT(5) ZEROFILL`, a value of 4 is retrieved as `00004`. Note that if you store larger values than the display width in an integer column, you may experience problems when MySQL generates temporary tables for some complicated joins, because in these cases MySQL trusts that the data did fit into the original column width.

All integer types can have an optional (non-standard) attribute `UNSIGNED`. Unsigned values can be used when you want to allow only non-negative numbers in a column and you need a bigger upper numeric range for the column.

As of MySQL 4.0.2, floating-point and fixed-point types also can be `UNSIGNED`. As with integer types, this attribute prevents negative values from being stored in the column. However, unlike the integer types, the upper range of column values remains the same.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

For floating-point column types, MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

The `FLOAT` type is used to represent approximate numeric data types. The SQL standard allows an optional specification of the precision (but not the range of the exponent) in bits following the keyword `FLOAT` in parentheses. The MySQL implementation also supports this optional precision specification, but the precision value is used only to determine storage size. A precision from 0 to 23 results in a four-byte single-precision `FLOAT` column. A precision from 24 to 53 results in an eight-byte double-precision `DOUBLE` column.

MySQL allows a non-standard syntax: `FLOAT(M,D)` or `REAL(M,D)` or `DOUBLE PRECISION(M,D)`. Here, "`(M,D)`" means than values are displayed with up to *M* decimal digits in total, of which *D* decimal digits may be after the decimal point. For example, a column defined as `FLOAT(7,4)` will look like `-999.9999` when displayed. MySQL performs rounding when storing values, so if you insert `999.00009` into a `FLOAT(7,4)` column, the approximate result is `999.0001`.

MySQL treats `DOUBLE` as a synonym for `DOUBLE PRECISION` (a non-standard extension). MySQL also treats `REAL` as a synonym for `DOUBLE PRECISION` (a non-standard variation), unless the server SQL mode includes the `REAL_AS_FLOAT` option.

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of decimal digits.

The `DECIMAL` and `NUMERIC` types are implemented as the same type by MySQL. They are used to store values for which it is important to preserve exact precision, for example with monetary data. When declaring a column of one of these types, the precision and scale can be (and usually is) specified; for example:

```
salary DECIMAL(5,2)
```

In this example, `5` is the precision and `2` is the scale. The precision represents the number of significant decimal digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

As of MySQL 5.0.3, `DECIMAL` and `NUMERIC` values are stored in binary format. Before 5.0.3, MySQL stores `DECIMAL` and `NUMERIC` values as strings, rather than in binary. One character is used for each digit of the value, the decimal point (if the scale is greater than 0), and the '`-`' sign (for negative numbers). If the scale is 0, `DECIMAL` and `NUMERIC` values contain no decimal point or fractional part.

Standard SQL requires that the `salary` column be able to store any value with five digits and two decimals. In this case, therefore, the range of values that can be stored in the `salary` column is

from -999.99 to 999.99. MySQL enforces this limit as of MySQL 5.0.3. Before 5.0.3, MySQL varies from this limit in two ways due to the use of string format for value storage:

- On the positive end of the range, the column actually can store numbers up to 9999.99. For positive numbers, MySQL uses the byte reserved for the sign to extend the upper end of the range.

- DECIMAL columns in MySQL before 3.23 are stored differently and cannot represent all the values required by standard SQL. This is because for a type of DECIMAL(*M*,*D*), the value of *M* includes the bytes for the sign and the decimal point. The range of the salary column before MySQL 3.23 would be -9.99 to 99.99.

In standard SQL, the syntax DECIMAL(*M*) is equivalent to DECIMAL(*M*,0). Similarly, the syntax DECIMAL is equivalent to DECIMAL(*M*,0), where the implementation is allowed to decide the value of *M*. As of MySQL 3.23.6, both of these variant forms of the DECIMAL and NUMERIC data types are supported. The default value of *M* is 10. Before 3.23.6, *M* and *D* both must be specified explicitly.

The maximum range of DECIMAL and NUMERIC values is the same as for DOUBLE, but the actual range for a given DECIMAL or NUMERIC column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are allowed by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the allowable number of digits.)

As of MySQL 5.0.3, the BIT data type can be used to store bit-field values. A type of BIT(*M*) allows for storage of *M*-bit values. *M* can range from 1 to 64.

To specify bit values, b'*value*' notation can be used. *value* is a binary value written using 0s and 1s. For example, b'111' and b'100000000' represent 7 and 128, respectively. See Section 9.1.5, "Bit-Field Values".

If you assign a value to a BIT(*M*) column that is less than *M* bits long, the value is padded on the left with 0-valued bits. For example, assigning a value of b'101' to a BIT(6) column is, in effect, the same as assigning b'000101'.

When asked to store a value in a numeric column that is outside the column type's allowable range, MySQL clips the value to the appropriate endpoint of the range and stores the resulting value instead.

For example, the range of an INT column is -2147483648 to 2147483647. If you try to insert -9999999999 into an INT column, MySQL clips the value to the lower endpoint of the range and stores -2147483648 instead. Similarly, if you try to insert 9999999999, MySQL clips the value to the upper endpoint of the range and stores 2147483647 instead.

If the INT column is UNSIGNED, the size of the column's range is the same but its endpoints shift up to 0 and 4294967295. If you try to store -9999999999 and 9999999999, the values stored in the column are 0 and 4294967296.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding end point of that range.

Conversions that occur due to clipping are reported as "warnings" for ALTER TABLE, LOAD DATA INFILE, UPDATE, and multiple-row INSERT statements.

11.3. Date and Time Types

The date and time types for representing temporal values are DATETIME, DATE, TIMESTAMP, TIME, and YEAR. Each temporal type has a range of legal values, as well as a "zero" value that is used when you specify an illegal value that MySQL cannot represent. The TIMESTAMP type has special automatic updating behavior, described later on.

Starting from MySQL 5.0.2, MySQL gives warnings/errors if you try to insert an illegal date. You can get MySQL to accept certain dates, such as `'1999-11-31'`, by using the `AL-LOW_INVALID_DATES` SQL mode. (Before 5.0.2, this mode was the default behavior for MySQL). This is useful when you want to store the "possibly wrong" value the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 0 to 12 and that the day is in the range from 0 to 31. These ranges are defined to include zero because MySQL allows you to store dates where the day or month and day are zero in a `DATE` or `DATETIME` column. This is extremely useful for applications that need to store a birthdate for which you don't know the exact date. In this case, you simply store the date as `'1999-00-00'` or `'1999-01-00'`. If you store dates such as these, you should not expect to get correct results for functions such as `DATE_SUB()` or `DATE_ADD` that require complete dates. (If you don't want to allow zero in dates, you can use the `NO_ZERO_IN_DATE` SQL mode).

MySQL also allows you to store `'0000-00-00'` as a "dummy date" (if you are not using the `NO_ZERO_DATE` SQL mode). This is in some cases is more convenient (and uses less space in data and index) than using `NULL` values.

By setting the `sql_mode` system variable to the appropriate mode values, You can more exactly what kind of dates you want MySQL to support. See Section 5.3.2, "The Server SQL Mode".

Here are some general considerations to keep in mind when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). Only the formats described in the following sections are supported. It is expected that you supply legal values, and unpredictable results may occur if you use values in other formats.

- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using the following rules:

  - Year values in the range `00-69` are converted to `2000-2069`.

  - Year values in the range `70-99` are converted to `1970-1999`.

- Although MySQL tries to interpret values in several formats, dates always must be given in year-month-day order (for example, `'98-09-04'`), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, `'09-04-98'`, `'04-09-98'`).

- MySQL automatically converts a date or time type value to a number if the value is used in a numeric context and vice versa.

- When MySQL encounters a value for a date or time type that is out of range or otherwise illegal for the type (as described at the beginning of this section), it converts the value to the "zero" value for that type. The exception is that out-of-range `TIME` values are clipped to the appropriate endpoint of the `TIME` range.

  The following table shows the format of the "zero" value for each type. Note that the use of these values produces warnings if the `NO_ZERO_DATE` SQL mode is enabled.

Column Type	"Zero" Value
DATETIME	`'0000-00-00 00:00:00'`
DATE	`'0000-00-00'`
TIMESTAMP	`00000000000000`
TIME	`'00:00:00'`
YEAR	`0000`

- The "zero" values are special, but you can store or refer to them explicitly using the values

shown in the table. You can also do this using the values `'0'` or 0, which are easier to write.

- "Zero" date or time values used through MyODBC are converted automatically to NULL in My-ODBC 2.50.12 and above, because ODBC can't handle such values.

11.3.1. The `DATETIME`, `DATE`, and `TIMESTAMP` Types

The DATETIME, DATE, and TIMESTAMP types are related. This section describes their characteristics, how they are similar, and how they differ.

The DATETIME type is used when you need values that contain both date and time information. MySQL retrieves and displays DATETIME values in `'YYYY-MM-DD HH:MM:SS'` format. The supported range is `'1000-01-01 00:00:00'` to `'9999-12-31 23:59:59'`. ("Supported" means that although earlier values might work, there is no guarantee)

The DATE type is used when you need only a date value, without a time part. MySQL retrieves and displays DATE values in `'YYYY-MM-DD'` format. The supported range is `'1000-01-01'` to `'9999-12-31'`.

The TIMESTAMP column type has varying properties, depending on the MySQL version and the SQL mode the server is running in. These properties are described later in this section.

You can specify DATETIME, DATE, and TIMESTAMP values using any of a common set of formats:

- As a string in either `'YYYY-MM-DD HH:MM:SS'` or `'YY-MM-DD HH:MM:SS'` format. A "relaxed" syntax is allowed: Any punctuation character may be used as the delimiter between date parts or time parts. For example, `'98-12-31 11:30:45'`, `'98.12.31 11+30+45'`, `'98/12/31 11*30*45'`, and `'98@12@31 11^30^45'` are equivalent.

- As a string in either `'YYYY-MM-DD'` or `'YY-MM-DD'` format. A "relaxed" syntax is allowed here, too. For example, `'98-12-31'`, `'98.12.31'`, `'98/12/31'`, and `'98@12@31'` are equivalent.

- As a string with no delimiters in either `'YYYYMMDDHHMMSS'` or `'YYMMDDHHMMSS'` format, provided that the string makes sense as a date. For example, `'19970523091528'` and `'970523091528'` are interpreted as `'1997-05-23 09:15:28'`, but `'971122129015'` is illegal (it has a nonsensical minute part) and becomes `'0000-00-00 00:00:00'`.

- As a string with no delimiters in either `'YYYYMMDD'` or `'YYMMDD'` format, provided that the string makes sense as a date. For example, `'19970523'` and `'970523'` are interpreted as `'1997-05-23'`, but `'971332'` is illegal (it has nonsensical month and day parts) and becomes `'0000-00-00'`.

- As a number in either YYYYMMDDHHMMSS or YYMMDDHHMMSS format, provided that the number makes sense as a date. For example, 19830905132800 and 830905132800 are interpreted as `'1983-09-05 13:28:00'`.

- As a number in either YYYYMMDD or YYMMDD format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as `'1983-09-05'`.

- As the result of a function that returns a value that is acceptable in a DATETIME, DATE, or TIMESTAMP context, such as NOW() or CURRENT_DATE.

Illegal DATETIME, DATE, or TIMESTAMP values are converted to the "zero" value of the appropriate type (`'0000-00-00 00:00:00'`, `'0000-00-00'`, or 00000000000000).

For values specified as strings that include date part delimiters, it is not necessary to specify two digits for month or day values that are less than 10. `'1979-6-9'` is the same as `'1979-06-09'`. Similarly, for values specified as strings that include time part delimiters, it is not necessary to spe-

cify two digits for hour, minute, or second values that are less than `10`. `'1979-10-30 1:2:3'` is the same as `'1979-10-30 01:02:03'`.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in `YYYYMMDD` or `YYYYMMDDHHMMSS` format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in `YYMMDD` or `YYMMDDH-HMMSS` format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as non-delimited strings are interpreted using their length as given. If the string is 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify `'9903'`, thinking that represents March, 1999, MySQL inserts a "zero" date into your table. This is because the year and month values are `99` and `03`, but the day part is completely missing, so the value is not a legal date. However, as of MySQL 3.23, you can explicitly specify a value of zero to represent missing month or day parts. For example, you can use `'990300'` to insert the value `'1999-03-00'`.

You can to some extent assign values of one date type to an object of a different date type. However, there may be some alteration of the value or loss of information:

- If you assign a `DATE` value to a `DATETIME` or `TIMESTAMP` object, the time part of the resulting value is set to `'00:00:00'` because the `DATE` value contains no time information.

- If you assign a `DATETIME` or `TIMESTAMP` value to a `DATE` object, the time part of the resulting value is deleted because the `DATE` type stores no time information.

- Remember that although `DATETIME`, `DATE`, and `TIMESTAMP` values all can be specified using the same set of formats, the types do not all have the same range of values. For example, `TIMESTAMP` values cannot be earlier than `1970` or later than `2037`. This means that a date such as `'1968-01-01'`, while legal as a `DATETIME` or `DATE` value, is not a valid `TIMESTAMP` value and is converted to `0` if assigned to such an object.

Be aware of certain pitfalls when specifying date values:

- The relaxed format allowed for values specified as strings can be deceiving. For example, a value such as `'10:11:12'` might look like a time value because of the ':' delimiter, but if used in a date context is interpreted as the year `'2010-11-12'`. The value `'10:45:15'` is converted to `'0000-00-00'` because `'45'` is not a legal month.

- The MySQL server performs only basic checking on the validity of a date: The ranges for year, month, and day are 1000 to 9999, 00 to 12, and 00 to 31, respectively. Any date containing parts not within these ranges is subject to conversion to `'0000-00-00'`. Please note that this still allows you to store invalid dates such as `'2002-04-31'`. To ensure that a date is valid, perform a check in your application.

- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using the following rules:

  - Year values in the range `00-69` are converted to `2000-2069`.

  - Year values in the range `70-99` are converted to `1970-1999`.

11.3.1.1. `TIMESTAMP` Properties Prior to MySQL 4.1

The `TIMESTAMP` column type provides a type that you can use to automatically mark `INSERT` or `UPDATE` operations with the current date and time. If you have multiple `TIMESTAMP` columns in a table, only the first one is updated automatically. (From MySQL 4.1.2 on, you can specify which

TIMESTAMP column updates; see Section 11.3.1.2, "TIMESTAMP Properties as of MySQL 4.1".)

Automatic updating of the first TIMESTAMP column in a table occurs under any of the following conditions:

- You explicitly set the column to NULL.

- The column is not specified explicitly in an INSERT or LOAD DATA INFILE statement.

- The column is not specified explicitly in an UPDATE statement and some other column changes value. An UPDATE that sets a column to the value it does not cause the TIMESTAMP column to be updated; if you set a column to its current value, MySQL ignores the update for efficiency.

A TIMESTAMP column other than the first also can be assigned the current date and time by setting it to NULL or to any function that produces the current date and time (NOW(), CUR-RENT_TIMESTAMP).

You can set any TIMESTAMP column to a value different from the current date and time by setting it explicitly to the desired value. This is true even for the first TIMESTAMP column. You can use this property if, for example, you want a TIMESTAMP to be set to the current date and time when you create a row, but not to be changed whenever the row is updated later:

- Let MySQL set the column when the row is created. This initializes it to the current date and time.

- When you perform subsequent updates to other columns in the row, set the TIMESTAMP column explicitly to its current value:

```
UPDATE tbl_name
    SET timestamp_col = timestamp_col,
        other_col1 = new_value1,
        other_col2 = new_value2, ...
```

Another way to maintain a column that records row-creation time is to use a DATETIME column that you initialize to NOW() when the row is created and do not modify for subsequent updates.

TIMESTAMP values may range from the beginning of 1970 to partway through the year 2037, with a resolution of one second. Values are displayed as numbers. When you store a value in a TIMESTAMP column, it is assumed to be represented in the current time zone, and is converted to UTC for storage. When you retrieve the value, it is converted from UTC back to the local time zone for display. Before MySQL 4.1.3, the server has a single time zone. As of 4.1.3, clients can set their time zone on a per-connection basis, as described in Time zone support.

The format in which MySQL retrieves and displays TIMESTAMP values depends on the display size, as illustrated by the following table. The "full" TIMESTAMP format is 14 digits, but TIMESTAMP columns may be created with shorter display sizes:

Column Type	Display Format
TIMESTAMP(14)	YYYYMMDDHHMMSS
TIMESTAMP(12)	YYMMDDHHMMSS
TIMESTAMP(10)	YYMMDDHHMM
TIMESTAMP(8)	YYYYMMDD
TIMESTAMP(6)	YYMMDD
TIMESTAMP(4)	YYMM
TIMESTAMP(2)	YY

All `TIMESTAMP` columns have the same storage size, regardless of display size. The most common display sizes are 6, 8, 12, and 14. You can specify an arbitrary display size at table creation time, but values of 0 or greater than 14 are coerced to 14. Odd-valued sizes in the range from 1 to 13 are coerced to the next higher even number.

`TIMESTAMP` columns store legal values using the full precision with which the value was specified, regardless of the display size. This has several implications:

- Always specify year, month, and day, even if your column types are `TIMESTAMP(4)` or `TIMESTAMP(2)`. Otherwise, the value is not a legal date and `0` is stored.

- If you use `ALTER TABLE` to widen a narrow `TIMESTAMP` column, information is displayed that previously was "hidden."

- Similarly, narrowing a `TIMESTAMP` column does not cause information to be lost, except in the sense that less information is shown when the values are displayed.

- If you are planning to use `mysqldump` for the database, do not use `TIMESTAMP(4)` or `TIMESTAMP(2)`. The display format for these column types are not legal dates and `0` will be stored instead. This inconsistency is fixed starting with MySQL 4.1, where display width is ignored. To prepare for transition to versions after 4.0, you should change to use display widths of 6 or more, which will produce a legal display format. You can change the display width of `TIMESTAMP` column types, without losing any information, by using `ALTER TABLE` as indicated above.

  If you need to print the timestamps for external applications, you can use `MID()` to extract the relevant part of the timestamp: for example, to imitate the `TIMESTAMP(4)` display format.

- Although `TIMESTAMP` values are stored to full precision, the only function that operates directly on the underlying stored value is `UNIX_TIMESTAMP()`. Other functions operate on the formatted retrieved value. This means you cannot use a function such as `HOUR()` or `SECOND()` unless the relevant part of the `TIMESTAMP` value is included in the formatted value. For example, the `HH` part of a `TIMESTAMP` column is not displayed unless the display size is at least 10, so trying to use `HOUR()` on shorter `TIMESTAMP` values produces a meaningless result.

In MySQL 4.1, `TIMESTAMP` display format changes to be the same as `DATETIME`, that is, as a string in `'YYYY-MM-DD HH:MM:SS'` format rather than as a number in `YYYYMMDDHHMMSS` format. To test applications written for MySQL 4.0 for compatibility with this change, you can set the `new` system variable to 1. This variable is available beginning with MySQL 4.0.12. It can be set at server startup by specifying the `--new` option to `mysqld`. At runtime, a user who has the `SUPER` privilege can set the global value with a `SET` statement:

```
mysql> SET GLOBAL new = 1;
```

Any client can set its session value of `new` as follows:

```
mysql> SET new = 1;
```

The general effect of setting `new` to 1 is that values for a `TIMESTAMP` column display as strings rather than as numbers. Also, `DESCRIBE` displays the column definition as `timestamp(19)`, rather than as `timestamp(14)`.

However, the effect differs somewhat for `TIMESTAMP` columns that are created while `new` is set to 1. In this case, column values display as strings and `DESCRIBE` shows the definition as `timestamp(19)`, regardless of the current value of `new`.

In other words, with `new=1`, all `TIMESTAMP` values display as strings and `DESCRIBE` shows a display width of 19. For columns created while `new=1`, they continue to display as strings and to have a display width of 19 even if `new` is set to 0.

For a TIMESTAMP column that displays as a string, you can display it as a number by retrieving it as *col_name*+0.

11.3.1.2. **TIMESTAMP** Properties as of MySQL 4.1

In MySQL 4.1 and up, the properties of the TIMESTAMP column type change in the ways described in this section.

From MySQL 4.1.0 on, TIMESTAMP display format differs from that of earlier MySQL releases:

- TIMESTAMP columns are displayed in the same format as DATETIME columns. In other words, the display width is fixed at 19 characters, and the format is YYYY-MM-DD HH:MM:SS.

- Display widths (used as described in the preceding section) are no longer supported. In other words, for declarations such as TIMESTAMP(2), TIMESTAMP(4), and so on, the display width is ignored.

Beginning with MySQL 4.1.1, the MySQL server can be run in MAXDB mode. When the server runs in this mode, TIMESTAMP is identical with DATETIME. That is, if the server is running in MAXDB mode at the time that a table is created, TIMESTAMP columns are created as DATETIME columns. As a result, such columns use DATETIME display format, have the same range of values, and there is no automatic initialization or updating to the current date and time.

To enable MAXDB mode, set the server SQL mode to MAXDB at startup using the --sql-mode=MAXDB server option or by setting the global sql_mode variable at runtime:

```
mysql> SET GLOBAL sql_mode=MAXDB;
```

A client can cause the server to run in MAXDB mode for its own connection as follows:

```
mysql> SET SESSION sql_mode=MAXDB;
```

As of MySQL 5.0.2, MySQL does not accept timestamp values that include a zero in the day or month column or values that are not a valid date. (The exception is the special value '0000-00-00 00:00:00'.)

Beginning with MySQL 4.1.2, you have more flexible control over when automatic TIMESTAMP initialization and updating occur and which column should have those behaviors:

- You can assign the current timestamp as the default value and the auto-update value, as before. But it is possible to have just one automatic behavior or the other, or neither of them. (It is not possible to have one behavior for one column and the other for another column.)

- You can specify which TIMESTAMP column to automatically initialize or update to the current date and time. This no longer need be the first TIMESTAMP column.

The following discussion describes the revised syntax and behavior. Note that this information applies only to TIMESTAMP columns for tables not created with MAXDB mode enabled. As noted earlier in this section, MAXDB mode causes columns to be created as DATETIME columns.

The following items summarize the pre-4.1.2 properties for TIMESTAMP initialization and updating:

The first TIMESTAMP column in table row automatically is set to the current timestamp when the record is created if the column is set to NULL or is not specified at all.

The first TIMESTAMP column in table row automatically is updated to the current timestamp when the value of any other column in the row is changed, unless the TIMESTAMP column explicitly is

assigned a value other than NULL.

If a DEFAULT value is specified for the first TIMESTAMP column when the table is created, it is silently ignored.

Other TIMESTAMP columns in the table can be set to the current TIMESTAMP by assigning NULL to them, but they do not update automatically.

As of 4.1.2, you have more flexibility in deciding which TIMESTAMP column automatically is initialized and updated to the current timestamp. The rules are as follows:

If a DEFAULT value is specified for the first TIMESTAMP column in a table, it is not ignored. The default can be CURRENT_TIMESTAMP or a constant date and time value.

DEFAULT NULL is the same as DEFAULT CURRENT_TIMESTAMP for the *first* TIMESTAMP column. For any other TIMESTAMP column, DEFAULT NULL is treated as DEFAULT 0.

Any single TIMESTAMP column in a table can be set to be the one that is initialized to the current timestamp and/or updated automatically.

In a CREATE TABLE statement, the first TIMESTAMP column can be declared in any of the following ways:

- With both DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP clauses, the column has the current timestamp for its default value, and is automatically updated.

- With neither DEFAULT nor ON UPDATE clauses, it is the same as DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP.

- With a DEFAULT CURRENT_TIMESTAMP clause and no ON UPDATE clause, the column has the current timestamp for its default value but is not automatically updated.

- With no DEFAULT clause and with an ON UPDATE CURRENT_TIMESTAMP clause, the column has a default of 0 and is automatically updated.

- With a constant DEFAULT value, the column has the given default. If the column has an ON UPDATE CURRENT_TIMESTAMP clause, it is automatically updated, otherwise not.

In other words, you can use the current timestamp for both the initial value and the auto-update value, or either one, or neither. (For example, you can specify ON UPDATE to get auto-update without also having the column auto-initialized.)

Any of CURRENT_TIMESTAMP, CURRENT_TIMESTAMP(), or NOW() can be used in the DEFAULT and ON UPDATE clauses. They all have the same effect.

The order of the two attributes does not matter. If both DEFAULT and ON UPDATE are specified for a TIMESTAMP column, either can precede the other.

Example. These statements are equivalent:

```
CREATE TABLE t (ts TIMESTAMP);
CREATE TABLE t (ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP
                             ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t (ts TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
                             DEFAULT CURRENT_TIMESTAMP);
```

To specify automatic default or updating for a TIMESTAMP column other than the first one, you must suppress the automatic initialization and update behaviors for the first TIMESTAMP column by explicitly assigning it a constant DEFAULT value (for example, DEFAULT 0 or DEFAULT '2003-01-01 00:00:00'). Then for the other TIMESTAMP column, the rules are the same as for the first TIMESTAMP column, except that you cannot omit both of the DEFAULT and ON UPDATE clauses. If you do that, no automatic initialization or updating occurs.

Example. These statements are equivalent:

```
CREATE TABLE t (
    ts1 TIMESTAMP DEFAULT 0,
    ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
                  ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t (
    ts1 TIMESTAMP DEFAULT 0,
    ts2 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
                  DEFAULT CURRENT_TIMESTAMP);
```

Beginning with MySQL 4.1.3, you can set the current time zone on a per-connection basis, as described in `Time zone support`. `TIMESTAMP` values still are stored in UTC, but are converted from the current time zone for storage, and converted back to the current time zone for retrieval. As long as the time zone setting remains the same, you get back the same value you store. If you store a `TIMESTAMP` value, then change the time zone and retrieve the value, it is different than the value you stored. This occurs because the same time zone is not used for conversion in both directions. The current time zone is available as the value of the `time_zone` system variable.

Beginning with MySQL 4.1.6, you can include the `NULL` attribute in the definition of a `TIMESTAMP` column to allow the column to contain `NULL` values. For example:

```
CREATE TABLE t
(
  ts1 TIMESTAMP NULL DEFAULT NULL,
  ts2 TIMESTAMP NULL DEFAULT 0,
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
);
```

Before MySQL 4.1.6 (and even as of 4.1.6 if the `NULL` attribute is not specified), setting the column to `NULL` sets it to the current timestamp. Note that a `TIMESTAMP` column which allows `NULL` values will **not** take on the current timestamp unless either its default value is defined as `CUR‐RENT_TIMESTAMP`, **or** either `NOW()` or `CURRENT_TIMESTAMP` is inserted into the column. In other words, a `TIMESTAMP` column defined as `NULL` will auto-update only if it defined using a definition such as the following:

```
CREATE TABLE t (ts NULL DEFAULT CURRENT_TIMESTAMP);
```

Otherwise - that is, if the `TIMESTAMP` column is defined using `NULL` but not using `DEFAULT TIMESTAMP`, as shown here:

```
CREATE TABLE t1 (ts NULL DEFAULT NULL);
CREATE TABLE t2 (ts NULL DEFAULT '0000-00-00 00:00:00');
```

then you must explicitly insert a value corresponding to the current date and time, for example:

```
INSERT INTO t1 VALUES (NOW());
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
```

11.3.2. The `TIME` Type

MySQL retrieves and displays `TIME` values in `'HH:MM:SS'` format (or `'HHH:MM:SS'` format for large hours values). `TIME` values may range from `'-838:59:59'` to `'838:59:59'`. The reason the hours part may be so large is that the `TIME` type may be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

You can specify `TIME` values in a variety of formats:

- As a string in `'D HH:MM:SS.fraction'` format. You can also use one of the following "relaxed" syntaxes: `'HH:MM:SS.fraction'`, `'HH:MM:SS'`, `'HH:MM'`, `'D HH:MM:SS'`, `'D HH:MM'`, `'D HH'`, or `'SS'`. Here `D` represents days and can have a value from 0 to 34. Note that MySQL doesn't yet store the fraction part.

- As a string with no delimiters in `'HHMMSS'` format, provided that it makes sense as a time. For example, `'101112'` is understood as `'10:11:12'`, but `'109712'` is illegal (it has a nonsensical minute part) and becomes `'00:00:00'`.

- As a number in `HHMMSS` format, provided that it makes sense as a time. For example, `101112` is understood as `'10:11:12'`. The following alternative formats are also understood: `SS`, `MMSS`, `HHMMSS`, `HHMMSS.fraction`. Note that MySQL doesn't yet store the fraction part.

- As the result of a function that returns a value that is acceptable in a `TIME` context, such as `CURRENT_TIME`.

For `TIME` values specified as strings that include a time part delimiter, it is not necessary to specify two digits for hours, minutes, or seconds values that are less than `10`. `'8:3:2'` is the same as `'08:03:02'`.

Be careful about assigning "short" `TIME` values to a `TIME` column. Without colons, MySQL interprets values using the assumption that the rightmost digits represent seconds. (MySQL interprets `TIME` values as elapsed time rather than as time of day.) For example, you might think of `'1112'` and `1112` as meaning `'11:12:00'` (12 minutes after 11 o'clock), but MySQL interprets them as `'00:11:12'` (11 minutes, 12 seconds). Similarly, `'12'` and `12` are interpreted as `'00:00:12'`. `TIME` values with colons, by contrast, are always treated as time of the day. That is `'11:12'` mean `'11:12:00'`, not `'00:11:12'`.

Values that lie outside the `TIME` range but are otherwise legal are clipped to the closest endpoint of the range. For example, `'-850:00:00'` and `'850:00:00'` are converted to `'-838:59:59'` and `'838:59:59'`.

Illegal `TIME` values are converted to `'00:00:00'`. Note that because `'00:00:00'` is itself a legal `TIME` value, there is no way to tell, from a value of `'00:00:00'` stored in a table, whether the original value was specified as `'00:00:00'` or whether it was illegal.

11.3.3. The `YEAR` Type

The `YEAR` type is a one-byte type used for representing years.

MySQL retrieves and displays `YEAR` values in `YYYY` format. The range is `1901` to `2155`.

You can specify `YEAR` values in a variety of formats:

- As a four-digit string in the range `'1901'` to `'2155'`.

- As a four-digit number in the range `1901` to `2155`.

- As a two-digit string in the range `'00'` to `'99'`. Values in the ranges `'00'` to `'69'` and `'70'` to `'99'` are converted to `YEAR` values in the ranges `2000` to `2069` and `1970` to `1999`.

- As a two-digit number in the range `1` to `99`. Values in the ranges `1` to `69` and `70` to `99` are converted to `YEAR` values in the ranges `2001` to `2069` and `1970` to `1999`. Note that the range for two-digit numbers is slightly different from the range for two-digit strings, because you cannot specify zero directly as a number and have it be interpreted as `2000`. You must specify it as a string `'0'` or `'00'` or it is interpreted as `0000`.

- As the result of a function that returns a value that is acceptable in a `YEAR` context, such as `NOW()`.

Illegal YEAR values are converted to 0000.

11.3.4. Y2K Issues and Date Types

MySQL itself is year 2000 (Y2K) safe (see Section 1.4.5, "Year 2000 Compliance"), but input values presented to MySQL may not be. Any input containing two-digit year values is ambiguous, because the century is unknown. Such values must be interpreted into four-digit form because MySQL stores years internally using four digits.

For DATETIME, DATE, TIMESTAMP, and YEAR types, MySQL interprets dates with ambiguous year values using the following rules:

- Year values in the range 00-69 are converted to 2000-2069.

- Year values in the range 70-99 are converted to 1970-1999.

Remember that these rules provide only reasonable guesses as to what your data values mean. If the heuristics used by MySQL do not produce the correct values, you should provide unambiguous input containing four-digit year values.

ORDER BY properly sorts TIMESTAMP or YEAR values that have two-digit years.

Some functions like MIN() and MAX() convert a TIMESTAMP or YEAR to a number. This means that a value with a two-digit year does not work properly with these functions. The fix in this case is to convert the TIMESTAMP or YEAR to four-digit year format or use something like MIN(DATE_ADD(timestamp,INTERVAL 0 DAYS)).

11.4. String Types

The string types are CHAR, VARCHAR, BINARY, VARBINARY, BLOB, TEXT, ENUM, and SET. This section describes how these types work and how to use them in your queries.

11.4.1. The CHAR and VARCHAR Types

The CHAR and VARCHAR types are similar, but differ in the way they are stored and retrieved. As of MySQL 5.0.3, they also differ in maximum length and in whether trailing spaces are retained.

The CHAR and VARCHAR types are declared with a length that indicates the maximum number of characters you want to store. For example, CHAR(30) can hold up to 30 characters. (Before MySQL 4.1, the length is interpreted as number of bytes.)

The length of a CHAR column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. (Before MySQL 3.23, the length of CHAR may be from 1 to 255.) When CHAR values are stored, they are right-padded with spaces to the specified length. When CHAR values are retrieved, trailing spaces are removed.

Values in VARCHAR columns are variable-length strings. The length can be specified as 1 to 255 before MySQL 4.0.2, 0 to 255 as of MySQL 4.0.2, and 0 to 65,535 as of MySQL 5.0.3. (The maximum actual length of a VARCHAR in MySQL 5.0 is determined by the maximum row size and the character set you use. The maximum effective length is 65,532 bytes.)

In contrast to CHAR, VARCHAR values are stored using only as many characters as are needed, plus one byte to record the length (two bytes for columns that are declared with a length longer than 255).

VARCHAR values are not padded when they are stored. Handling of trailing spaces is version-dependent. As of MySQL 5.0.3, trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL. Before MySQL 5.0.3, trailing spaces are removed from values when they are stored into a VARCHAR column; this means the spaces also are absent from retrieved

values.

No lettercase conversion takes place during storage or retrieval.

If you assign a value to a CHAR or VARCHAR column that exceeds the column's maximum length, the value is truncated to fit. If the truncated characters are not spaces, a warning is generated. You can cause an error to occur rather than an warning by using "strict" SQL mode. See Section 5.3.2, "The Server SQL Mode".

Before MySQL 5.0.3, if you need a data type for which trailing spaces are not removed, consider using a BLOB or TEXT type. Also, if you want to store binary values such as results from an encryption or compression function that might contain arbitrary byte values, use a BLOB column rather than a CHAR or VARCHAR column, to avoid potential problems with trailing space removal that would change data values.

The following table illustrates the differences between the two types of columns by showing the result of storing various string values into CHAR(4) and VARCHAR(4) columns:

Value	CHAR(4)	Storage Required	VARCHAR(4)	Storage Required
''	' '	4 bytes	''	1 byte
'ab'	'ab '	4 bytes	'ab'	3 bytes
'abcd'	'abcd'	4 bytes	'abcd'	5 bytes
'abcdefgh'	'abcd'	4 bytes	'abcd'	5 bytes

The values retrieved from the CHAR(4) and VARCHAR(4) columns are the same in each case, because trailing spaces are removed from CHAR columns upon retrieval.

As of MySQL 4.1, values in CHAR and VARCHAR columns are sorted and compared according to the collation of the character set assigned to the column. Before MySQL 4.1, sorting and comparison are based on the collation of the server character set; you can declare the column with the BIN-ARY attribute to cause sorting and comparison to be based on the numeric values of the bytes in column values. BINARY doesn't affect how column values are stored or retrieved.

The BINARY attribute is sticky. This means that if a column marked BINARY is used in an expression, the whole expression is treated as a BINARY value.

From MySQL 4.1.0 on, column type CHAR BYTE is an alias for CHAR BINARY. This is a compatibility feature.

From MySQL 4.1.0 on, the ASCII attribute can be specified for CHAR. It assigns the latin1 character set.

From MySQL 4.1.1 on, the UNICODE attribute can be specified for CHAR. It assigns the ucs2 character set.

MySQL may silently change the type of a CHAR or VARCHAR column at table creation time. See Section 13.1.5.1, "Silent Column Specification Changes".

11.4.2. The BINARY and VARBINARY Types

The BINARY and VARBINARY types are similar to CHAR and VARCHAR, except that they contain binary strings rather than non-binary strings. That is, they contain byte strings rather than character strings. This means they have no character set, and sorting and comparison is based on the numeric values of the bytes in column values.

The allowable maximum length is the same for BINARY and VARBINARY as it is for CHAR and VARCHAR, except that the length for BINARY and VARBINARY is a length in bytes rather than in characters.

The handling of trailing spaces is the same for BINARY and VARBINARY as it is for CHAR and VARCHAR. When BINARY values are stored, they are right-padded with spaces to the specified

length. When `BINARY` values are retrieved, trailing spaces are removed. For `VARBINARY`, trailing spaces are removed when values are stored. As of MySQL 5.0.3, trailing spaces are retained. You should consider these characteristics if you plan to use these data types for storing binary data that might end with spaces.

Before MySQL 4.1.2, `BINARY(M)` and `VARBINARY(M)` are treated as `CHAR(M) BINARY` and `VARCHAR(M) BINARY`. As of MySQL 4.1.2, `BINARY` and `VARBINARY` are available as distinct data types, and for `CHAR(M) BINARY` and `VARCHAR(M) BINARY`, the `BINARY` attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary collation for the column character set to be used, but the column itself contains non-binary character strings rather than binary byte strings. For example, in 4.1 and up, `CHAR(5) BINARY` is treated as `CHAR(5) CHARACTER SET latin1 COLLATE latin1_bin`, assuming that the default character set is `latin1`.

11.4.3. The `BLOB` and `TEXT` Types

A `BLOB` is a binary large object that can hold a variable amount of data. The four `BLOB` types, `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`, differ only in the maximum length of the values they can hold.

See Section 11.5, "Column Type Storage Requirements".

The four `TEXT` types, `TINYTEXT`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`, correspond to the four `BLOB` types and have the same maximum lengths and storage requirements.

`BLOB` columns are treated as binary strings (byte strings). `TEXT` columns are treated as non-binary strings (character strings). `BLOB` columns have no character set, and sorting and comparison is based on the numeric values of the bytes in column values. `TEXT` columns have a character set, and values are sorted and compared based on the collation of the character set assigned to the column as of MySQL 4.1. Before 4.1, `TEXT` sorting and comparison are based on the collation of the server character set.

No lettercase conversion takes place during storage or retrieval.

If you assign a value to a `BLOB` or `TEXT` column that exceeds the column type's maximum length, the value is truncated to fit. If the truncated characters are not spaces, a warning is generated. You can cause an error to occur rather than an warning by using "strict" SQL mode. See Section 5.3.2, "The Server SQL Mode".

In most respects, you can regard a `BLOB` column as a `VARBINARY` column that can be as big as you like. Similarly, you can regard a `TEXT` column as a `VARCHAR` column. `BLOB` and `TEXT` differ from `VARBINARY` and `VARCHAR` in the following ways::

- There is no trailing-space removal for `BLOB` and `TEXT` columns when values are stored or retrieved. Before MySQL 5.0.3, this differs from `VARBINARY` and `VARCHAR`, for which trailing spaces are removed when values are stored.

  Note that `TEXT` is on comparison space extended to fit the compared object, exactly like `CHAR` and `VARCHAR`.

- You can have indexes on `BLOB` and `TEXT` columns only as of MySQL 3.23.2 for `MyISAM` tables or MySQL 4.0.14 for `InnoDB` tables. Older versions of MySQL did not support indexing these column types.

- For indexes on `BLOB` and `TEXT` columns, you must specify an index prefix length. For `CHAR` and `VARCHAR`, a prefix length is optional.

- `BLOB` and `TEXT` columns cannot have `DEFAULT` values.

From MySQL 4.1.0 on, `LONG` and `LONG VARCHAR` map to the `MEDIUMTEXT` data type. This is a compatibility feature. If you use the `BINARY` attribute with a `TEXT` column type, the column is assigned the binary collation of the column character set.

MySQL Connector/ODBC defines `BLOB` values as `LONGVARBINARY` and `TEXT` values as `LONGVARCHAR`.

Because `BLOB` and `TEXT` values may be extremely long, you may encounter some constraints in using them:

• Only the first `max_sort_length` bytes of the column are used when sorting. The default value of `max_sort_length` is 1024; this value can be changed using the `--max_sort_length` option when starting the `mysqld` server. See Section 5.3.3, "Server System Variables".

  As of MySQL 4.0.3, you can make more bytes significant in sorting or grouping by increasing the value of `max_sort_length` at runtime. Any client can change the value of its session `max_sort_length` variable:

  ```
  mysql> SET max_sort_length = 2000;
  mysql> SELECT id, comment FROM tbl_name
      -> ORDER BY comment;
  ```

  Another way to use `GROUP BY` or `ORDER BY` on a `BLOB` or `TEXT` column containing long values when you want more than `max_sort_length` bytes to be significant is to convert the column value into a fixed-length object. The standard way to do this is with the `SUBSTRING` function. For example, the following statement causes 2000 bytes of the `comment` column to be taken into account for sorting:

  ```
  mysql> SELECT id, SUBSTRING(comment,1,2000) FROM tbl_name
      -> ORDER BY SUBSTRING(comment,1,2000);
  ```

  Before MySQL 3.23.2, you can group on an expression involving `BLOB` or `TEXT` values by using a column alias or by specifying the column position:

  ```
  mysql> SELECT id, SUBSTRING(comment,1,2000) AS b
      -> FROM tbl_name GROUP BY b;
  mysql> SELECT id, SUBSTRING(comment,1,2000)
      -> FROM tbl_name GROUP BY 2;
  ```

• The maximum size of a `BLOB` or `TEXT` object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the `max_allowed_packet` variable, but you must do so for both the server and your client program. For example, both `mysql` and `mysqldump` allow you to change the client-side `max_allowed_packet` value. See Section 7.5.2, "Tuning Server Parameters", Section 8.3, "mysql — The MySQL Command-Line Tool", and Section 8.8, "mysqldump — A Database Backup Program".

Each `BLOB` or `TEXT` value is represented internally by a separately allocated object. This is in contrast to all other column types, for which storage is allocated once per column when the table is opened.

11.4.4. The `ENUM` Type

An `ENUM` is a string object with a value chosen from a list of allowed values that are enumerated explicitly in the column specification at table creation time.

The value may also be the empty string (`''`) or `NULL` under certain circumstances:

• If you insert an invalid value into an `ENUM` (that is, a string not present in the list of allowed values), the empty string is inserted instead as a special error value. This string can be distinguished

from a "normal" empty string by the fact that this string has the numerical value 0. More about this later.

- If an ENUM column is declared to allow NULL, the NULL value is a legal value for the column, and the default value is NULL. If an ENUM column is declared NOT NULL, its default value is the first element of the list of allowed values.

Each enumeration value has an index:

- Values from the list of allowable elements in the column specification are numbered beginning with 1.

- The index value of the empty string error value is 0. This means that you can use the following SELECT statement to find rows into which invalid ENUM values were assigned:

  ```
  mysql> SELECT * FROM tbl_name WHERE enum_col=0;
  ```

- The index of the NULL value is NULL.

For example, a column specified as ENUM('one', 'two', 'three') can have any of the values shown here. The index of each value is also shown:

Value	Index
NULL	NULL
''	0
'one'	1
'two'	2
'three'	3

An enumeration can have a maximum of 65,535 elements.

Starting from MySQL 3.23.51, trailing spaces are automatically deleted from ENUM member values when the table is created.

When retrieved, values stored into an ENUM column are displayed using the lettercase that was used in the column definition. Before MySQL 4.1.1, lettercase is irrelevant when you assign values to an ENUM column. As of 4.1.1, ENUM columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase does matter when you assign values to to the column.

If you retrieve an ENUM value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an ENUM column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

If you store a number into an ENUM column, the number is treated as an index, and the value stored is the enumeration member with that index. (However, this does not work with LOAD DATA, which treats all input as strings.) It's not advisable to define an ENUM column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of '0', '1', and '2', but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

ENUM values are sorted according to the order in which the enumeration members were listed in the column specification. (In other words, ENUM values are sorted according to their index numbers.)

For example, `'a'` sorts before `'b'` for ENUM(`'a'`, `'b'`), but `'b'` sorts before `'a'` for ENUM(`'b'`, `'a'`). The empty string sorts before non-empty strings, and NULL values sort before all other enumeration values. To prevent unexpected results, specify the ENUM list in alphabetical order. You can also use GROUP BY CAST(col AS VARCHAR) or GROUP BY CON-CAT(col) to make sure that the column is sorted lexically rather than by index number.

If you want to determine all possible values for an ENUM column, use SHOW COLUMNS FROM *tbl_name* LIKE *enum_col* and parse the ENUM definition in the second column of the output.

11.4.5. The `SET` Type

A `SET` is a string object that can have zero or more values, each of which must be chosen from a list of allowed values specified when the table is created. SET column values that consist of multiple set members are specified with members separated by commas (','). A consequence of this is that SET member values cannot themselves contain commas.

For example, a column specified as SET(`'one'`, `'two'`) NOT NULL can have any of these values:

```
''
'one'
'two'
'one,two'
```

A `SET` can have a maximum of 64 different members.

Starting from MySQL 3.23.51, trailing spaces are automatically deleted from SET member values when the table is created.

When retrieved, values stored into a SET column are displayed using the lettercase that was used in the column definition. Before MySQL 4.1.1, lettercase is irrelevant when you assign values to an SET column. As of 4.1.1, SET columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase does matter when you assign values to to the column.

MySQL stores SET values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a SET value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a SET column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a SET column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as SET(`'a'`,`'b'`,`'c'`,`'d'`), the members have the following decimal and binary values:

SET **Member**	**Decimal Value**	**Binary Value**
`'a'`	1	0001
`'b'`	2	0010
`'c'`	4	0100
`'d'`	8	1000

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth SET value members `'a'` and `'d'` are selected and the resulting value is `'a,d'`.

For a value containing more than one SET element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. For example, suppose a column is specified as SET(`'a'`,`'b'`,`'c'`,`'d'`):

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

and insert the values `'a,d'`, `'d,a'`, `'a,d,d'`, `'a,d,a'`, and `'d,a,d'`:

```
mysql> INSERT INTO myset (col) VALUES
-> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5  Duplicates: 0  Warnings: 0
```

then all of these values appear as `'a,d'` when retrieved:

```
mysql> SELECT col FROM myset;
+------+
| col  |
+------+
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
+------+
5 rows in set (0.04 sec)
```

If you set a `SET` column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
+---------+------+------------------------------------------+
| Level   | Code | Message                                  |
+---------+------+------------------------------------------+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+---------+------+------------------------------------------+
1 row in set (0.04 sec)

mysql> SELECT col FROM myset;
+------+
| col  |
+------+
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
+------+
6 rows in set (0.01 sec)
```

`SET` values are sorted numerically. `NULL` values sort before non-`NULL` `SET` values.

Normally, you search for `SET` values using the `FIND_IN_SET()` function or the `LIKE` operator:

```
mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value',set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';
```

The first statement finds rows where `set_col` contains the `value` set member. The second is similar, but not the same: It finds rows where `set_col` contains `value` anywhere, even as a substring of another set member.

The following statements also are legal:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to `'val1,val2'` returns different results than comparing values to `'val2,val1'`. You should specify the values in the same order they are listed in the column definition.

If you want to determine all possible values for a SET column, use SHOW COLUMNS FROM `tbl_name` LIKE `set_col` and parse the SET definition in the second column of the output.

11.5. Column Type Storage Requirements

The storage requirements for each of the column types supported by MySQL are listed by category.

The maximum size of a row in a MyISAM table is 65,534 bytes. Each BLOB and TEXT column accounts for only five to nine bytes toward this size.

If a MyISAM or ISAM table includes any variable-length column types, the record format is also variable length. When a table is created, MySQL may, under certain conditions, change a column from a variable-length type to a fixed-length type or vice versa. See Section 13.1.5.1, "Silent Column Specification Changes".

Storage Requirements for Numeric Types

Column Type	Storage Required
TINYINT	1 byte
SMALLINT	2 bytes
MEDIUMINT	3 bytes
INT, INTEGER	4 bytes
BIGINT	8 bytes
FLOAT(p)	4 bytes if $0 <= p <= 24$, 8 bytes if $25 <= p <= 53$
FLOAT	4 bytes
DOUBLE [PRECISION], item REAL	8 bytes
DECIMAL(M,D), NUMERIC(M,D)	Varies; see following discussion
BIT(M)	approximately (M+7)/8 bytes

The storage requirements for DECIMAL (and NUMERIC) are version-specific:

As of MySQL 5.0.3, values for DECIMAL columns longer are represented using a binary format that packs nine decimal digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the "leftover" digits require some fraction of four bytes. The storage required for "leftover" digits is given by the following table:

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3
6	3
7	4

8	4
9	4

Before MySQL 5.0.3, `DECIMAL` columns are represented as strings and storage requirements are: M+2 bytes if $D > 0$, M+1 bytes if $D = 0$ (D+2, if $M < D$)

Storage Requirements for Date and Time Types

Column Type	Storage Required
`DATE`	3 bytes
`DATETIME`	8 bytes
`TIMESTAMP`	4 bytes
`TIME`	3 bytes
`YEAR`	1 byte

Storage Requirements for String Types

Column Type	Storage Required
`CHAR(M)`	M bytes, $0 <= M <= 255$
`VARCHAR(M)`	L+1 bytes, where $L <= M$ and $0 <= M <= 255$ before MySQL 5.0.3 ($0 <= M <= 65535$ in MySQL 5.0.3 and later — see note below)
`BINARY(M)`	M bytes, $0 <= M <= 255$
`VARBINARY(M)`	L+1 bytes, where $L <= M$ and $0 <= M <= 255$
`TINYBLOB, TINYTEXT`	L+1 bytes, where $L < 2^8$
`BLOB, TEXT`	L+2 bytes, where $L < 2^{16}$
`MEDIUMBLOB, MEDIUMTEXT`	L+3 bytes, where $L < 2^{24}$
`LONGBLOB, LONGTEXT`	L+4 bytes, where $L < 2^{32}$
`',...` `ENUM('value1','value2)`	1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)
`SET('value1','value2',...)`	1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)

`VARCHAR` and the `BLOB` and `TEXT` types are variable-length types. For each, the storage requirements depend on the actual length of column values (represented by L in the preceding table), rather than on the type's maximum possible size. For example, a `VARCHAR(10)` column can hold a string with a maximum length of 10. The actual storage required is the length of the string (L), plus 1 byte to record the length of the string. For the string `'abcd'`, L is 4 and the storage requirement is 5 bytes.

For the `CHAR`, `VARCHAR`, and `TEXT` types, L and M in the preceding table should be interpreted as number of bytes before MySQL 4.1 and as number of characters thereafter. Lengths for these types in columns specifications indicate number of characters from MySQL 4.1 on. The number of extra bytes for recording lengths for variable-length data types is unchanged. For example, L+1 bytes to store a `TINYTEXT` value before MySQL 4.1 becomes L characters + 1 byte to store the length as of MySQL 4.1.

Note: In MySQL 5.0.3 and later, the *effective* maximum length for a `VARCHAR` column is 65,532 characters.

As of MySQL 5.0.3, the `NDBCLUSTER` engine supports only fixed-width columns. This means that a `VARCHAR` column from a table in a MySQL Cluster will behave almost as if it were of type `CHAR`

(except that each record still has one extra byte overhead). For example, in a Cluster table, *each* record in a column declared as `VARCHAR(100)` will take up 101 bytes for storage, regardless of the length of the string actually stored in any given record.

The `BLOB` and `TEXT` types require 1, 2, 3, or 4 bytes to record the length of the column value, depending on the maximum possible length of the type. See Section 11.4.3, "The `BLOB` and `TEXT` Types".

`TEXT` and `BLOB` columns are implemented differently in the NDB Cluster storage engine, wherein each record in a `TEXT` column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which stored in a hidden table. The records in this second table are always 2,000 bytes long. This means that the size of a `TEXT` column is 256 if $size <= 256$ (where $size$ represents the size of the record); otherwise, the size is $256 + size + (2000 - (size - 256) \% 2000)$.

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations with up to 65,535 values. See Section 11.4.4, "The `ENUM` Type".

The size of a `SET` object is determined by the number of different set members. If the set size is N, the object occupies $(N+7)/8$ bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See Section 11.4.5, "The `SET` Type".

11.6. Choosing the Right Type for a Column

For the most efficient use of storage, try to use the most precise type in all cases. For example, if an integer column is used for values in the range from `1` to `99999`, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, it uses the least amount of storage.

Tables created with MySQL 5.0.3 and above uses a a new storage format for `DECIMAL` columns. All basic calculation (`+`,`-`,`*`,`/`) with `DECIMAL` columns are done with precision of 64 decimal digits. See Section 11.1.1, "Overview of Numeric Types".

For earlier MySQL version, accurate representation of monetary values was a common problem. In these MySQL version, you should also use the `DECIMAL` type. In this case the value is stored as a string, so no loss of accuracy should occur on storage. Calculations on these `DECIMAL` values are however done using double-precision operations. If accuracy is not too important or if speed is important, the `DOUBLE` type may also be good enough.

For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This allows you to do all calculations with 64-bit integers and convert results back to floating-point values only when necessary.

11.7. Using Column Types from Other Database Engines

To make it easier to use code written for SQL implementations from other vendors, MySQL maps column types as shown in the following table. These mappings make it easier to import table definitions from other database engines into MySQL:

Other Vendor Type	MySQL Type
`BINARY(M)`	`CHAR(M) BINARY` (before MySQL 4.1.2)
`BOOL`	`TINYINT`
`BOOLEAN`	`TINYINT`
`CHAR VARYING(M)`	`VARCHAR(M)`
`DEC`	`DECIMAL`
`FIXED`	`DECIMAL` (MySQL 4.1.0 on)
`FLOAT4`	`FLOAT`

`FLOAT8`	`DOUBLE`
`INT1`	`TINYINT`
`INT2`	`SMALLINT`
`INT3`	`MEDIUMINT`
`INT4`	`INT`
`INT8`	`BIGINT`
`LONG VARBINARY`	`MEDIUMBLOB`
`LONG VARCHAR`	`MEDIUMTEXT`
`LONG`	`MEDIUMTEXT` (MySQL 4.1.0 on)
`MIDDLEINT`	`MEDIUMINT`
`NUMERIC`	`DECIMAL`
`VARBINARY(M)`	`VARCHAR(M) BINARY` (before MySQL 4.1.2)

As of MySQL 4.1.2, `BINARY` and `VARBINARY` are distinct data types and are not converted to `CHAR BINARY` and `VARCHAR BINARY`.

Column type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE` `tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types.

Chapter 12. Functions and Operators

Expressions can be used at several points in SQL statements, such as in the `ORDER BY` or `HAVING` clauses of `SELECT` statements, in the `WHERE` clause of a `SELECT`, `DELETE`, or `UPDATE` statement, or in `SET` statements. Expressions can be written using literal values, column values, `NULL`, functions, and operators. This chapter describes the functions and operators that are allowed for writing expressions in MySQL.

An expression that contains `NULL` always produces a `NULL` value unless otherwise indicated in the documentation for a particular function or operator.

Note: By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. Spaces around function arguments are permitted, though.

You can tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` option. Individual client programs can request this behavior by using the `CLIENT_IGNORE_SPACE` option for `mysql_real_connect()`. In either case, all function names become reserved words. See Section 5.3.2, "The Server SQL Mode".

For the sake of brevity, most examples in this chapter display the output from the `mysql` program in abbreviated form. Instead of showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----------+
| mod(29,9) |
+-----------+
|         2 |
+-----------+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
        -> 2
```

12.1. Operators

12.1.1. Operator Precedence

Operator precedences are shown in the following list, from lowest precedence to the highest. Operators that are shown together on a line have the same precedence.

```
:=
||, OR, XOR
&&, AND
NOT
BETWEEN, CASE, WHEN, THEN, ELSE
=, <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN
|
&
<<, >>
-, +
*, /, DIV, %, MOD
^
- (unary minus), ~ (unary bit inversion)
!
BINARY, COLLATE
```

The precedence shown for `NOT` is as of MySQL 5.0.2. For earlier versions, or from 5.0.2 on if the `HIGH_NOT_PRECEDENCE` SQL mode is enabled, the precedence of `NOT` is the same as that of the `!` operator. See Section 5.3.2, "The Server SQL Mode".

12.1.2. Parentheses

- `( ... )`

  Use parentheses to force the order of evaluation in an expression. For example:

  ```
  mysql> SELECT 1+2*3;
          -> 7
  mysql> SELECT (1+2)*3;
          -> 9
  ```

12.1.3. Comparison Functions and Operators

Comparison operations result in a value of `1` (TRUE), `0` (FALSE), or `NULL`. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

Some of the functions in this section (such as `LEAST()` and `GREATEST()`) return values other than `1` (TRUE), `0` (FALSE), or `NULL`. However, the value they return is based on comparison operations performed as described by the following rules.

MySQL compares values using the following rules:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL`-safe `<=>` equality comparison operator.

- If both arguments in a comparison operation are strings, they are compared as strings.

- If both arguments are integers, they are compared as integers.

- Hexadecimal values are treated as binary strings if not compared to a number.

-
  If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. Note that this is not done for arguments in `IN()`! To be safe, always use complete datetime/date/time strings when doing comparisons.

- In all other cases, the arguments are compared as floating-point (real) numbers.

By default, string comparisons are not case sensitive and use the current character set (cp1252 Latin1 by default, which also works excellently for English).

To convert a value to a specific type for comparison purposes, you can use the `CAST()` function. String values can be converted to a different character set using `CONVERT()`. See Section 12.8, "Cast Functions and Operators".

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
        -> 0
mysql> SELECT 7 > '6x';
        -> 1
mysql> SELECT 0 > 'x6';
        -> 0
```

```
mysql> SELECT 0 = 'x6';
        -> 1
```

Note that when you are comparing a string column with a number, MySQL can't use an index on the column to quickly look up the value. If *str_col* is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value 1: '1', ' 1', '1a', ...

- =

  Equal:

  ```
  mysql> SELECT 1 = 0;
          -> 0
  mysql> SELECT '0' = 0;
          -> 1
  mysql> SELECT '0.0' = 0;
          -> 1
  mysql> SELECT '0.01' = 0;
          -> 0
  mysql> SELECT '.01' = 0.01;
          -> 1
  ```

- <=>

  NULL-safe equal. This operator performs an equality comparison like the = operator, but returns 1 rather than NULL if both operands are NULL, and 0 rather than NULL if one operand is NULL.

  ```
  mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
          -> 1, 1, 0
  mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
          -> 1, NULL, NULL
  ```

  <=> was added in MySQL 3.23.0.

- <> , !=

  Not equal:

  ```
  mysql> SELECT '.01' <> '0.01';
          -> 1
  mysql> SELECT .01 <> '0.01';
          -> 0
  mysql> SELECT 'zapp' <> 'zappp';
          -> 1
  ```

-

  <=

  Less than or equal:

  ```
  mysql> SELECT 0.1 <= 2;
          -> 1
  ```

-

```
<
```

Less than:

```
mysql> SELECT 2 < 2;
        -> 0
```

- ```
  >=
  ```

  Greater than or equal:

  ```
  mysql> SELECT 2 >= 2;
          -> 1
  ```

- ```
  >
  ```

  Greater than:

  ```
  mysql> SELECT 2 > 2;
          -> 0
  ```

- `IS boolean_value`, `IS NOT boolean_value`

  Tests whether a value against a boolean value, where `boolean_value` can be TRUE, FALSE, or UNKNOWN.

  ```
  mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
          -> 1, 1, 1
  mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
          -> 1, 1, 0
  ```

  `IS [NOT] boolean_value` syntax was added in MySQL 5.0.2.

- `IS NULL`, `IS NOT NULL`

  Tests whether a value is or is not NULL.

  ```
  mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
          -> 0, 0, 1
  mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
          -> 1, 1, 0
  ```

  To be able to work well with ODBC programs, MySQL supports the following extra features when using IS NULL:

  - You can find the row that contains the most recent AUTO_INCREMENT value by issuing a statement of the following form immediately after generating the value:

    ```
    SELECT * FROM tbl_name WHERE auto_col IS NULL
    ```

    This behavior can be disabled by setting SQL_AUTO_IS_NULL=0. See Section 13.5.3, "SET Syntax".

  - For DATE and DATETIME columns that are declared as NOT NULL, you can find the special date '0000-00-00' by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC doesn't support a `'0000-00-00'` date value.

-
  expr BETWEEN *min* AND *max*

  If *expr* is greater than or equal to *min* and *expr* is less than or equal to *max*, BETWEEN returns 1, otherwise it returns 0. This is equivalent to the expression (*min* <= *expr* AND *expr* <= *max*) if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described at the beginning of this section, but applied to all the three arguments. **Note**: Before MySQL 4.0.5, arguments were converted to the type of *expr* instead.

  ```
  mysql> SELECT 1 BETWEEN 2 AND 3;
          -> 0
  mysql> SELECT 'b' BETWEEN 'a' AND 'c';
          -> 1
  mysql> SELECT 2 BETWEEN 2 AND '3';
          -> 1
  mysql> SELECT 2 BETWEEN 2 AND 'x-3';
          -> 0
  ```

-
  expr NOT BETWEEN *min* AND *max*

  This is the same as NOT (*expr* BETWEEN *min* AND *max*).

- COALESCE(*value*,...)

  Returns the first non-NULL value in the list.

  ```
  mysql> SELECT COALESCE(NULL,1);
          -> 1
  mysql> SELECT COALESCE(NULL,NULL,NULL);
          -> NULL
  ```

  COALESCE() was added in MySQL 3.23.3.

-
  GREATEST(*value1*,*value2*,...)

  With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for LEAST().

  ```
  mysql> SELECT GREATEST(2,0);
          -> 2
  mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
          -> 767.0
  mysql> SELECT GREATEST('B','A','C');
          -> 'C'
  ```

  Before MySQL 5.0.13, GREATEST() returns NULL only if all arguments are NULL. As of 5.0.13, it returns NULL if any argument is NULL.

  Before MySQL 3.22.5, you can use MAX() instead of GREATEST().

-
  expr IN (*value*,...)

Returns 1 if `expr` is any of the values in the `IN` list, else returns 0. If all values are constants, they are evaluated according to the type of `expr` and sorted. The search for the item then is done using a binary search. This means `IN` is very quick if the `IN` value list consists entirely of constants. If `expr` is a case-sensitive string expression, the string comparison is performed in case-sensitive fashion.

```
mysql> SELECT 2 IN (0,3,5,'wefwf');
        -> 0
mysql> SELECT 'wefwf' IN (0,3,5,'wefwf');
        -> 1
```

The number of values in the `IN` list is only limited by the `max_allowed_packet` value.

To comply with the SQL standard, from MySQL 4.1 on `IN` returns `NULL` not only if the expression on the left hand side is `NULL`, but also if no match is found in the list and one of the expressions in the list is `NULL`.

From MySQL 4.1 on, `IN()` syntax also is used to write certain types of subqueries. See Section 13.2.8.3, "Subqueries with `ANY`, `IN`, and `SOME`".

•

```
expr NOT IN (value,...)
```

This is the same as `NOT (expr IN (value,...))`.

•

```
ISNULL(expr)
```

If `expr` is `NULL`, `ISNULL()` returns 1, otherwise it returns 0.

```
mysql> SELECT ISNULL(1+1);
        -> 0
mysql> SELECT ISNULL(1/0);
        -> 1
```

A comparison of `NULL` values using `=` is always false.

The `ISNULL()` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`.

•

```
INTERVAL(N,N1,N2,N3,...)
```

Returns 0 if $N < N1$, 1 if $N < N2$ and so on or -1 if N is `NULL`. All arguments are treated as integers. It is required that $N1 < N2 < N3 < \ldots < Nn$ for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
        -> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
        -> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
        -> 0
```

•

```
LEAST(value1,value2,...)
```

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules.

• If the return value is used in an `INTEGER` context or all arguments are integer-valued, they are compared as integers.

- If the return value is used in a `REAL` context or all arguments are real-valued, they are compared as reals.

- If any argument is a case-sensitive string, the arguments are compared as case-sensitive strings.

- In other cases, the arguments are compared as case-insensitive strings.

```
mysql> SELECT LEAST(2,0);
        -> 0
mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
        -> 3.0
mysql> SELECT LEAST('B','A','C');
        -> 'A'
```

Before MySQL 5.0.13, `LEAST()` returns `NULL` only if all arguments are `NULL`. As of 5.0.13, it returns `NULL` if any argument is `NULL`.

Before MySQL 3.22.5, you can use `MIN()` instead of `LEAST()`.

Note that the preceding conversion rules can produce strange results in some borderline cases:

```
mysql> SELECT CAST(LEAST(3600, 9223372036854775808.0) as SIGNED);
        -> -9223372036854775808
```

This happens because MySQL reads `9223372036854775808.0` in an integer context. The integer representation is not good enough to hold the value, so it wraps to a signed integer.

12.1.4. Logical Operators

In SQL, all logical operators evaluate to TRUE, FALSE, or `NULL` (UNKNOWN). In MySQL, these are implemented as `1` (TRUE), `0` (FALSE), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any non-zero value for TRUE.

- `NOT`, `!`

  Logical NOT. Evaluates to `1` if the operand is `0`, to `0` if the operand is non-zero, and `NOT NULL` returns `NULL`.

  ```
  mysql> SELECT NOT 10;
          -> 0
  mysql> SELECT NOT 0;
          -> 1
  mysql> SELECT NOT NULL;
          -> NULL
  mysql> SELECT ! (1+1);
          -> 0
  mysql> SELECT ! 1+1;
          -> 1
  ```

  The last example produces `1` because the expression evaluates the same way as `(!1)+1`.

- `AND`, `&&`

  Logical AND. Evaluates to `1` if all operands are non-zero and not `NULL`, to `0` if one or more operands are `0`, otherwise `NULL` is returned.

  ```
  mysql> SELECT 1 && 1;
  ```

```
            -> 1
mysql> SELECT 1 && 0;
        -> 0
mysql> SELECT 1 && NULL;
        -> NULL
mysql> SELECT 0 && NULL;
        -> 0
mysql> SELECT NULL && 0;
        -> 0
```

Please note that MySQL versions prior to 4.0.5 stop evaluation when a NULL is encountered, rather than continuing the process to check for possible 0 values. This means that in these versions, SELECT (NULL AND 0) returns NULL instead of 0. As of MySQL 4.0.5, the code has been re-engineered so that the result is always as prescribed by the SQL standards while still using the optimization wherever possible.

- OR, ||

  Logical OR. When both operands are non-NULL, the result is 1 if any operand is non-zero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is non-zero, and NULL otherwise. If both operands are NULL, the result is NULL.

  ```
  mysql> SELECT 1 || 1;
          -> 1
  mysql> SELECT 1 || 0;
          -> 1
  mysql> SELECT 0 || 0;
          -> 0
  mysql> SELECT 0 || NULL;
          -> NULL
  mysql> SELECT 1 || NULL;
          -> 1
  ```

- XOR

  Logical XOR. Returns NULL if either operand is NULL. For non-NULL operands, evaluates to 1 if an odd number of operands is non-zero, otherwise 0 is returned.

  ```
  mysql> SELECT 1 XOR 1;
          -> 0
  mysql> SELECT 1 XOR 0;
          -> 1
  mysql> SELECT 1 XOR NULL;
          -> NULL
  mysql> SELECT 1 XOR 1 XOR 1;
          -> 1
  ```

  a XOR b is mathematically equal to (a AND (NOT b)) OR ((NOT a) and b).

  XOR was added in MySQL 4.0.2.

12.2. Control Flow Functions

- CASE *value* WHEN [*compare-value*] THEN *result* [WHEN [*compare-value*] THEN *result* ...] [ELSE *result*] END , CASE WHEN [*condition*] THEN *result* [WHEN [*condition*] THEN *result* ...] [ELSE *result*] END

The first version returns the *result* where *value=compare-value*. The second version returns the result for the first condition that is true. If there was no matching result value, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

```
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
    ->     WHEN 2 THEN 'two' ELSE 'more' END;
        -> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
        -> 'true'
mysql> SELECT CASE BINARY 'B'
    ->     WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
        -> NULL
```

Before MySQL 4.1, the type of the return value (`INTEGER`, `DOUBLE`, or `STRING`) is the same as the type of the first returned value (the expression after the first `THEN`). From MySQL 4.1, the default return type is the compatible aggregated type of all return values.

Note that `CASE` evaluation depends also on the context in which it is used. If used in string context, the result is returned as a string. If used in numeric context, the result is returned decimal, real, or integer value.

`CASE` was added in MySQL 3.23.3.

-

  `IF(expr1,expr2,expr3)`

  If *expr1* is TRUE (*expr1* `<> 0` and *expr1* `<> NULL`) then `IF()` returns *expr2*, else it returns *expr3*. `IF()` returns a numeric or string value, depending on the context in which it is used.

```
mysql> SELECT IF(1>2,2,3);
        -> 3
mysql> SELECT IF(1<2,'yes','no');
        -> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
        -> 'no'
```

If only one of `expr2` or `expr3` is explicitly `NULL`, the result type of the `IF()` function is the type of non-`NULL` expression. (This behavior is new in MySQL 4.0.3.)

`expr1` is evaluated as an integer value, which means that if you are testing floating-point or string values, you should do so using a comparison operation.

```
mysql> SELECT IF(0.1,1,0);
        -> 0
mysql> SELECT IF(0.1<>0,1,0);
        -> 1
```

In the first case shown, `IF(0.1)` returns `0` because `0.1` is converted to an integer value, resulting in a test of `IF(0)`. This may not be what you expect. In the second case, the comparison tests the original floating-point value to see whether it is non-zero. The result of the comparison is used as an integer.

The default return type of `IF()` (which may matter when it is stored into a temporary table) is calculated in MySQL 3.23 as follows:

Expression	Return Value
`expr2` or `expr3` returns a string	string
`expr2` or `expr3` returns a floating-point value	floating-point
`expr2` or `expr3` returns an integer	integer

If `expr2` and `expr3` are strings, the result is case sensitive if either string is case sensitive (starting from MySQL 3.23.51).

- `IFNULL(expr1,expr2)`

  If `expr1` is not `NULL`, `IFNULL()` returns `expr1`, else it returns `expr2`. `IFNULL()` returns a numeric or string value, depending on the context in which it is used.

  ```
  mysql> SELECT IFNULL(1,0);
          -> 1
  mysql> SELECT IFNULL(NULL,10);
          -> 10
  mysql> SELECT IFNULL(1/0,10);
          -> 10
  mysql> SELECT IFNULL(1/0,'yes');
          -> 'yes'
  ```

  In MySQL 4.0.6 and above, the default result value of `IFNULL(expr1,expr2)` is the more "general" of the two expressions, in the order `STRING`, `REAL`, or `INTEGER`. The difference from earlier MySQL versions is mostly notable when you create a table based on expressions or MySQL has to internally store a value from `IFNULL()` in a temporary table.

  ```
  CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
  ```

  As of MySQL 4.0.6, the type for the `test` column is `CHAR(4)`, whereas in earlier versions the type would be `BIGINT`.

- `NULLIF(expr1,expr2)`

  Returns `NULL` if `expr1 = expr2` is true, else returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

  ```
  mysql> SELECT NULLIF(1,1);
          -> NULL
  mysql> SELECT NULLIF(1,2);
          -> 1
  ```

  Note that MySQL evaluates `expr1` twice if the arguments are not equal.

  `NULLIF()` was added in MySQL 3.23.15.

12.3. String Functions

String-valued functions return `NULL` if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See Section 7.5.2, "Tuning Server Parameters".

For functions that operate on string positions, the first position is numbered 1.

- `ASCII(str)`

  Returns the numeric value of the leftmost character of the string `str`. Returns `0` if `str` is the empty string. Returns `NULL` if `str` is `NULL`. `ASCII()` works for characters with numeric values from `0` to `255`.

  ```
  mysql> SELECT ASCII('2');
          -> 50
  mysql> SELECT ASCII(2);
  ```

```
            -> 50
mysql> SELECT ASCII('dx');
        -> 100
```

See also the `ORD()` function.

-

  `BIN(N)`

  Returns a string representation of the binary value of `N`, where `N` is a longlong (`BIGINT`) num-
  ber. This is equivalent to `CONV(N,10,2)`. Returns `NULL` if `N` is `NULL`.

  ```
  mysql> SELECT BIN(12);
          -> '1100'
  ```

-

  `BIT_LENGTH(str)`

  Returns the length of the string `str` in bits.

  ```
  mysql> SELECT BIT_LENGTH('text');
          -> 32
  ```

  `BIT_LENGTH()` was added in MySQL 4.0.2.

-

  `CHAR(N,...)`

  `CHAR()` interprets the arguments as integers and returns a string consisting of the characters
  given by the code values of those integers. `NULL` values are skipped.

  ```
  mysql> SELECT CHAR(77,121,83,81,'76');
          -> 'MySQL'
  mysql> SELECT CHAR(77,77.3,'77.3');
          -> 'MMM'
  ```

-

  `CHAR_LENGTH(str)`

  Returns the length of the string `str`, measured in characters. A multi-byte character counts as a
  single character. This means that for a string containing five two-byte characters, `LENGTH()` re-
  turns `10`, whereas `CHAR_LENGTH()` returns `5`.

-

  `CHARACTER_LENGTH(str)`

  `CHARACTER_LENGTH()` is a synonym for `CHAR_LENGTH()`.

-

  `COMPRESS(string_to_compress)`

  Compresses a string. This function requires MySQL to have been compiled with a compression
  library such as `zlib`. Otherwise, the return value is always `NULL`. The compressed string can
  be uncompressed with `UNCOMPRESS()`.

  ```
  mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
          -> 21
  mysql> SELECT LENGTH(COMPRESS(''));
          -> 0
  mysql> SELECT LENGTH(COMPRESS('a'));
          -> 13
  mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
  ```

```
        -> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.

- Non-empty strings are stored as a four-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra '.' character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (Use of `CHAR` or `VARCHAR` to store compressed strings is not recommended. It is better to use a `BLOB` column instead.)

`COMPRESS()` was added in MySQL 4.1.1.

-
  `CONCAT(str1,str2,...)`

  Returns the string that results from concatenating the arguments. Returns `NULL` if any argument is `NULL`. May have one or more arguments. If all arguments are non-binary strings, the result is a non-binary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent binary string form; if you want to avoid that you can use explicit type cast, like in this example: `SELECT CONCAT(CAST(int_col AS CHAR), char_col)`

  ```
  mysql> SELECT CONCAT('My', 'S', 'QL');
          -> 'MySQL'
  mysql> SELECT CONCAT('My', NULL, 'QL');
          -> NULL
  mysql> SELECT CONCAT(14.3);
          -> '14.3'
  ```

-
  `CONCAT_WS(separator,str1,str2,...)`

  `CONCAT_WS()` stands for CONCAT With Separator and is a special form of `CONCAT()`. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string as can the rest of the arguments. If the separator is `NULL`, the result is `NULL`. The function skips any `NULL` values after the separator argument.

  ```
  mysql> SELECT CONCAT_WS(',','First name','Second name','Last Name');
          -> 'First name,Second name,Last Name'
  mysql> SELECT CONCAT_WS(',','First name',NULL,'Last Name');
          -> 'First name,Last Name'
  ```

  Before MySQL 4.0.14, `CONCAT_WS()` skips empty strings as well as `NULL` values.

-
  `CONV(N,from_base,to_base)`

  Converts numbers between different number bases. Returns a string representation of the number N, converted from base `from_base` to base `to_base`. Returns `NULL` if any argument is `NULL`. The argument N is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If `to_base` is a negative number, N is regarded as a signed number. Otherwise, N is treated as unsigned. `CONV()` works with 64-bit precision.

  ```
  mysql> SELECT CONV('a',16,2);
          -> '1010'
  mysql> SELECT CONV('6E',18,8);
          -> '172'
  mysql> SELECT CONV(-17,10,-18);
  ```

```
          -> '-H'
mysql> SELECT CONV(10+'10'+'10'+0xa,10,10);
          -> '40'
```

- ELT(*N*,*str1*,*str2*,*str3*,...)

  Returns *str1* if *N* = 1, *str2* if *N* = 2, and so on. Returns NULL if *N* is less than 1 or greater than the number of arguments. ELT() is the complement of FIELD().

  ```
  mysql> SELECT ELT(1, 'ej', 'Heja', 'hej', 'foo');
          -> 'ej'
  mysql> SELECT ELT(4, 'ej', 'Heja', 'hej', 'foo');
          -> 'foo'
  ```

- EXPORT_SET(*bits*,*on*,*off*[,*separator*[,*number_of_bits*]])

  Returns a string in which for every bit set in the value *bits*, you get an *on* string and for every reset bit you get an *off* string. Bits in *bits* are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the *separator* string (default ','). The number of bits examined is given by *number_of_bits* (default 64).

  ```
  mysql> SELECT EXPORT_SET(5,'Y','N',',',4);
          -> 'Y,N,Y,N'
  mysql> SELECT EXPORT_SET(6,'1','0',',',10);
          -> '0,1,1,0,0,0,0,0,0,0'
  ```

- FIELD(*str*,*str1*,*str2*,*str3*,...)

  Returns the index of *str* in the *str1*, *str2*, *str3*, ... list. Returns 0 if *str* is not found.

  If all arguments to FIELD() are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

  If *str* is NULL, the return value is 0 because NULL fails equality comparison with any value. FIELD() is the complement of ELT().

  ```
  mysql> SELECT FIELD('ej', 'Hej', 'ej', 'Heja', 'hej', 'foo');
          -> 2
  mysql> SELECT FIELD('fo', 'Hej', 'ej', 'Heja', 'hej', 'foo');
          -> 0
  ```

- FIND_IN_SET(*str*,*strlist*)

  Returns a value 1 to *N* if the string *str* is in the string list *strlist* consisting of *N* substrings. A string list is a string composed of substrings separated by ',' characters. If the first argument is a constant string and the second is a column of type SET, the FIND_IN_SET() function is optimized to use bit arithmetic. Returns 0 if *str* is not in *strlist* or if *strlist* is the empty string. Returns NULL if either argument is NULL. This function does not work properly if the first argument contains a comma (',') character.

  ```
  mysql> SELECT FIND_IN_SET('b','a,b,c,d');
          -> 2
  ```

- HEX(*N_or_S*)

  If *N_OR_S* is a number, returns a string representation of the hexadecimal value of *N*, where *N* is

a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,16)`.

From MySQL 4.0.1 and up, if `N_OR_S` is a string, returns a hexadecimal string of `N_OR_S` where each character in `N_OR_S` is converted to two hexadecimal digits.

```
mysql> SELECT HEX(255);
        -> 'FF'
mysql> SELECT 0x616263;
        -> 'abc'
mysql> SELECT HEX('abc');
        -> 616263
```

*
  `INSERT(str,pos,len,newstr)`

  Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string. Replaces the rest of the string from position `pos` is `len` is not within the length of the rest of the string. Returns `NULL` if any argument is null.

  ```
  mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
          -> 'QuWhattic'
  mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
          -> 'Quadratic'
  mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
          -> 'QuWhat'
  ```

  This function is multi-byte safe.

*
  `INSTR(str,substr)`

  Returns the position of the first occurrence of substring `substr` in string `str`. This is the same as the two-argument form of `LOCATE()`, except that the arguments are swapped.

  ```
  mysql> SELECT INSTR('foobarbar', 'bar');
          -> 4
  mysql> SELECT INSTR('xbar', 'foobar');
          -> 0
  ```

  This function is multi-byte safe. In MySQL 3.23, this function is case sensitive. For 4.0 on, it is case sensitive only if either argument is a binary string.

*
  `LCASE(str)`

  `LCASE()` is a synonym for `LOWER()`.

*
  `LEFT(str,len)`

  Returns the leftmost `len` characters from the string `str`.

  ```
  mysql> SELECT LEFT('foobarbar', 5);
          -> 'fooba'
  ```

*
  `LENGTH(str)`

  Returns the length of the string `str`, measured in bytes. A multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

```
mysql> SELECT LENGTH('text');
        -> 4
```

-

LOAD_FILE(*file_name*)

Reads the file and returns the file contents as a string. The file must be located on the server, you must specify the full pathname to the file, and you must have the FILE privilege. The file must be readable by all and be smaller than max_allowed_packet bytes.

If the file doesn't exist or cannot be read because one of the preceding conditions is not satisfied, the function returns NULL.

```
mysql> UPDATE tbl_name
            SET blob_column=LOAD_FILE('/tmp/picture')
            WHERE id=1;
```

Before MySQL 3.23, you must read the file inside your application and create an INSERT statement to update the database with the file contents. If you are using the MySQL++ library, one way to do this can be found in the MySQL++ manual, available at http://dev.mysql.com/doc/.

-

LOCATE(*substr*,*str*), LOCATE(*substr*,*str*,*pos*)

The first syntax returns the position of the first occurrence of substring *substr* in string *str*. The second syntax returns the position of the first occurrence of substring *substr* in string *str*, starting at position *pos*. Returns 0 if *substr* is not in *str*.

```
mysql> SELECT LOCATE('bar', 'foobarbar');
        -> 4
mysql> SELECT LOCATE('xbar', 'foobar');
        -> 0
mysql> SELECT LOCATE('bar', 'foobarbar',5);
        -> 7
```

This function is multi-byte safe. In MySQL 3.23, this function is case sensitive. For 4.0 on, it is case sensitive only if either argument is a binary string.

-

LOWER(*str*)

Returns the string *str* with all characters changed to lowercase according to the current character set mapping (the default is cp1252 Latin1).

```
mysql> SELECT LOWER('QUADRATICALLY');
        -> 'quadratically'
```

This function is multi-byte safe.

-

LPAD(*str*,*len*,*padstr*)

Returns the string *str*, left-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

```
mysql> SELECT LPAD('hi',4,'??');
        -> '??hi'
mysql> SELECT LPAD('hi',1,'??');
        -> 'h'
```

- LTRIM(*str*)

  Returns the string *str* with leading space characters removed.

  ```
  mysql> SELECT LTRIM('  barbar');
          -> 'barbar'
  ```

  This function is multi-byte safe.

- MAKE_SET(*bits*,*str1*,*str2*,...)

  Returns a set value (a string containing substrings separated by ',' characters) consisting of the strings that have the corresponding bit in *bits* set. *str1* corresponds to bit 0, *str2* to bit 1, and so on. NULL values in *str1*, *str2*, ... are not appended to the result.

  ```
  mysql> SELECT MAKE_SET(1,'a','b','c');
          -> 'a'
  mysql> SELECT MAKE_SET(1 | 4,'hello','nice','world');
          -> 'hello,world'
  mysql> SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
          -> 'hello'
  mysql> SELECT MAKE_SET(0,'a','b','c');
          -> ''
  ```

- MID(*str*,*pos*,*len*)

  MID(*str*,*pos*,*len*) is a synonym for SUBSTRING(*str*,*pos*,*len*).

- OCT(*N*)

  Returns a string representation of the octal value of *N*, where *N* is a longlong (BIGINT)number. This is equivalent to CONV(N,10,8). Returns NULL if *N* is NULL.

  ```
  mysql> SELECT OCT(12);
          -> '14'
  ```

- OCTET_LENGTH(*str*)

  OCTET_LENGTH() is a synonym for LENGTH().

- ORD(*str*)

  If the leftmost character of the string *str* is a multi-byte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

  ```
    (1st byte code)
  + (2nd byte code × 256)
  + (3rd byte code × 256²) ...
  ```

  If the leftmost character is not a multi-byte character, ORD() returns the same value as the AS-CII() function.

  ```
  mysql> SELECT ORD('2');
          -> 50
  ```

- POSITION(*substr* IN *str*)

  POSITION(*substr* IN *str*) is a synonym for LOCATE(*substr*,*str*).

- QUOTE(*str*)

  Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned surrounded by single quotes and with each instance of single quote ('' '), backslash ('\'), ASCII NUL, and Control-Z preceded by a backslash. If the argument is NULL, the return value is the word "NULL" without surrounding single quotes. The QUOTE() function was added in MySQL 4.0.3.

  ```
  mysql> SELECT QUOTE('Don\'t!');
          -> 'Don\'t!'
  mysql> SELECT QUOTE(NULL);
          -> NULL
  ```

- REPEAT(*str*,*count*)

  Returns a string consisting of the string *str* repeated *count* times. If *count* <= 0, returns an empty string. Returns NULL if *str* or *count* are NULL.

  ```
  mysql> SELECT REPEAT('MySQL', 3);
          -> 'MySQLMySQLMySQL'
  ```

- REPLACE(*str*,*from_str*,*to_str*)

  Returns the string *str* with all occurrences of the string *from_str* replaced by the string *to_str*.

  ```
  mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
          -> 'WwWwWw.mysql.com'
  ```

  This function is multi-byte safe.

- REVERSE(*str*)

  Returns the string *str* with the order of the characters reversed.

  ```
  mysql> SELECT REVERSE('abc');
          -> 'cba'
  ```

  This function is multi-byte safe.

- RIGHT(*str*,*len*)

  Returns the rightmost *len* characters from the string *str*.

  ```
  mysql> SELECT RIGHT('foobarbar', 4);
          -> 'rbar'
  ```

  This function is multi-byte safe.

- RPAD(*str*,*len*,*padstr*)

Returns the string `str`, right-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```
mysql> SELECT RPAD('hi',5,'?');
        -> 'hi???'
mysql> SELECT RPAD('hi',1,'?');
        -> 'h'
```

This function is multi-byte safe.

-
  RTRIM(`str`)

  Returns the string `str` with trailing space characters removed.

  ```
  mysql> SELECT RTRIM('barbar   ');
          -> 'barbar'
  ```

  This function is multi-byte safe.

-
  SOUNDEX(`str`)

  Returns a soundex string from `str`. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the SOUN-DEX() function returns an arbitrarily long string. You can use SUBSTRING() on the result to get a standard soundex string. All non-alphabetic characters are ignored in the given string. All international alphabetic characters outside the A-Z range are treated as vowels.

  ```
  mysql> SELECT SOUNDEX('Hello');
          -> 'H400'
  mysql> SELECT SOUNDEX('Quadratically');
          -> 'Q36324'
  ```

  Note: This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and then duplicates, whereas the enhanced version discards duplicates first and then vowels.

-
  `expr1` SOUNDS LIKE `expr2`

  This is the same as SOUNDEX(`expr1`) = SOUNDEX(`expr2`). It is available only in MySQL 4.1 or later.

-
  SPACE(`N`)

  Returns a string consisting of `N` space characters.

  ```
  mysql> SELECT SPACE(6);
          -> '      '
  ```

-
  SUBSTRING(`str`,`pos`)   ,   SUBSTRING(`str`   FROM   `pos`)   , SUBSTRING(`str`,`pos`,`len`),SUBSTRING(`str` FROM `pos` FOR `len`)

  The forms without a `len` argument return a substring from string `str` starting at position `pos`. The forms with a `len` argument return a substring `len` characters long from string `str`, starting at position `pos`. The forms that use FROM are standard SQL syntax. Beginning with MySQL 4.1, it is possible to use a negative value for `pos`. In this case, the beginning of the substring is `pos` characters from the end of the string, rather than the beginning. A negative value may be

used for *pos* in any of the forms of this function.

```
mysql> SELECT SUBSTRING('Quadratically',5);
        -> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
        -> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
        -> 'ratica'
mysql> SELECT SUBSTRING('Sakila', -3);
        -> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
        -> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
        -> 'ki'
```

This function is multi-byte safe.

Note that if you use a value less than than 1 for *len*, the result is always an empty string.

SUBSTR() is a synonym for SUBSTRING(), added in MySQL 4.1.1.

- SUBSTRING_INDEX(*str*,*delim*,*count*)

Returns the substring from string *str* before *count* occurrences of the delimiter *delim*. If *count* is positive, everything to the left of the final delimiter (counting from the left) is returned. If *count* is negative, everything to the right of the final delimiter (counting from the right) is returned.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
        -> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
        -> 'mysql.com'
```

This function is multi-byte safe.

- TRIM([{BOTH | LEADING | TRAILING} [*remstr*] FROM] *str*), TRIM(*remstr* FROM] *str*)

Returns the string *str* with all *remstr* prefixes and/or suffixes removed. If none of the specifiers BOTH, LEADING, or TRAILING is given, BOTH is assumed. *remstr* is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM('  bar   ');
        -> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');
        -> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
        -> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxxyz');
        -> 'barx'
```

This function is multi-byte safe.

- UCASE(*str*)

UCASE() is a synonym for UPPER().

- UNCOMPRESS(*string_to_uncompress*)

Uncompresses a string compressed by the COMPRESS() function. If the argument is not a com-

pressed value, the result is `NULL`. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
        -> 'any string'
mysql> SELECT UNCOMPRESS('any string');
        -> NULL
```

`UNCOMPRESS()` was added in MySQL 4.1.1.

-
  `UNCOMPRESSED_LENGTH(compressed_string)`

  Returns the length of a compressed string before compression.

  ```
  mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
          -> 30
  ```

  `UNCOMPRESSED_LENGTH()` was added in MySQL 4.1.1.

-
  `UNHEX(str)`

  Does the opposite of `HEX(str)`. That is, it interprets each pair of hexadecimal digits in the argument as a number and converts it to the character represented by the number. The resulting characters are returned as a binary string.

  ```
  mysql> SELECT UNHEX('4D7953514C');
          -> 'MySQL'
  mysql> SELECT 0x4D7953514C;
          -> 'MySQL'
  mysql> SELECT UNHEX(HEX('string'));
          -> 'string'
  mysql> SELECT HEX(UNHEX('1267'));
          -> '1267'
  ```

  `UNHEX()` was added in MySQL 4.1.2.

-
  `UPPER(str)`

  Returns the string `str` with all characters changed to uppercase according to the current character set mapping (the default is cp1252 Latin1).

  ```
  mysql> SELECT UPPER('Hej');
          -> 'HEJ'
  ```

  This function is multi-byte safe.

12.3.1. String Comparison Functions

MySQL automatically converts numbers to strings as necessary, and vice versa.

```
mysql> SELECT 1+'1';
        -> 2
mysql> SELECT CONCAT(2,' test');
      -> '2 test'
```

If you want to convert a number to a string explicitly, use the `CAST()` or `CONCAT()` function:

```
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
        -> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
        -> 38.8, '38.8'
```

CAST() is preferable, but it is unavailable before MySQL 4.0.2.

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case sensitive, the comparison is performed in case-sensitive fashion.

* *expr* LIKE *pat* [ESCAPE *'escape-char'*]

  Pattern matching using SQL simple regular expression comparison. Returns 1 (TRUE) or 0 (FALSE). If either *expr* or *pat* is NULL, the result is NULL.

  The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

  With LIKE you can use the following two wildcard characters in the pattern:

Character	Description
%	Matches any number of characters, even zero characters
_	Matches exactly one character

  ```
  mysql> SELECT 'David!' LIKE 'David_';
          -> 1
  mysql> SELECT 'David!' LIKE '%D%v%';
          -> 1
  ```

  To test for literal instances of a wildcard character, precede the character with the escape character. If you don't specify the ESCAPE character, '\' is assumed.

String	Description
\%	Matches one '%' character
_	Matches one '_' character

  ```
  mysql> SELECT 'David!' LIKE 'David\_';
          -> 0
  mysql> SELECT 'David_' LIKE 'David\_';
          -> 1
  ```

  To specify a different escape character, use the ESCAPE clause:

  ```
  mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
          -> 1
  ```

  The following two statements illustrate that string comparisons are not case sensitive unless one of the operands is a binary string:

  ```
  mysql> SELECT 'abc' LIKE 'ABC';
          -> 1
  mysql> SELECT 'abc' LIKE BINARY 'ABC';
          -> 0
  ```

In MySQL, `LIKE` is allowed on numeric expressions. (This is an extension to the standard SQL `LIKE`.)

```
mysql> SELECT 10 LIKE '1%';
        -> 1
```

Note: Because MySQL uses the C escape syntax in strings (for example, '\n' to represent newline), you must double any '\' that you use in your `LIKE` strings. For example, to search for '\n', specify it as '\\n'. To search for '\', specify it as '\\\\' (the backslashes are stripped once by the parser and another time when the pattern match is done, leaving a single backslash to be matched).

-
  expr NOT LIKE *pat* [ESCAPE *'escape-char'*]

  This is the same as NOT (*expr* LIKE *pat* [ESCAPE *'escape-char'*]).

-
  expr NOT REGEXP *pat*, *expr* NOT RLIKE *pat*

  This is the same as NOT (*expr* REGEXP *pat*).

- *expr* REGEXP *pat*, *expr* RLIKE *pat*

  Performs a pattern match of a string expression *expr* against a pattern *pat*. The pattern can be an extended regular expression. The syntax for regular expressions is discussed in Appendix H, *MySQL Regular Expressions*. Returns 1 if *expr* matches *pat*, otherwise returns 0. If either *expr* or *pat* is NULL, the result is NULL. RLIKE is a synonym for REGEXP, provided for mSQL compatibility.

  The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

  Note: Because MySQL uses the C escape syntax in strings (for example, '\n' to represent newline), you must double any '\' that you use in your REGEXP strings.

  As of MySQL 3.23.4, REGEXP is not case sensitive for normal (not binary) strings.

```
mysql> SELECT 'Monty!' REGEXP 'm%y%%';
        -> 0
mysql> SELECT 'Monty!' REGEXP '.*';
        -> 1
mysql> SELECT 'new*\n*line' REGEXP 'new\\*.\\*line';
        -> 1
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
        -> 1  0
mysql> SELECT 'a' REGEXP '^[a-d]';
        -> 1
```

REGEXP and RLIKE use the current character set (cp1252 Latin1 by default) when deciding the type of a character. However, these operators are not multi-byte safe.

-
  STRCMP(*expr1*,*expr2*)

  STRCMP() returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
        -> -1
mysql> SELECT STRCMP('text2', 'text');
```

```
        -> 1
mysql> SELECT STRCMP('text', 'text');
        -> 0
```

As of MySQL 4.0, STRCMP() uses the current character set when performing comparisons. This makes the default comparison behavior case insensitive unless one or both of the operands are binary strings. Before MySQL 4.0, STRCMP() is case sensitive.

12.4. Numeric Functions

12.4.1. Arithmetic Operators

The usual arithmetic operators are available. Note that in the case of -, +, and *, the result is calculated with BIGINT (64-bit) precision if both arguments are integers. If one of the arguments is an unsigned integer, and the other argument is also an integer, the result is an unsigned integer. See Section 12.8, "Cast Functions and Operators".

- +

  Addition:

  ```
  mysql> SELECT 3+5;
          -> 8
  ```

- −

  Subtraction:

  ```
  mysql> SELECT 3-5;
          -> -2
  ```

- −

  Unary minus. Changes the sign of the argument.

  ```
  mysql> SELECT - 2;
          -> -2
  ```

  Note that if this operator is used with a BIGINT, the return value is a BIGINT! This means that you should avoid using − on integers that may have the value of -2^{63}!

- *

  Multiplication:

  ```
  mysql> SELECT 3*5;
          -> 15
  mysql> SELECT 18014398509481984*18014398509481984.0;
          -> 324518553658426726783156020576256.0
  mysql> SELECT 18014398509481984*18014398509481984;
          -> 0
  ```

  The result of the last expression is incorrect because the result of the integer multiplication exceeds the 64-bit range of BIGINT calculations.

- /

Division:

```
mysql> SELECT 3/5;
        -> 0.60
```

Division by zero produces a NULL result:

```
mysql> SELECT 102/(1-1);
        -> NULL
```

A division is calculated with BIGINT arithmetic only if performed in a context where its result are converted to an integer.

- DIV

Integer division. Similar to FLOOR() but safe with BIGINT values.

```
mysql> SELECT 5 DIV 2;
        -> 2
```

DIV is new in MySQL 4.1.0.

12.4.2. Mathematical Functions

All mathematical functions return NULL in case of an error.

- ABS(*X*)

Returns the absolute value of *X*.

```
mysql> SELECT ABS(2);
        -> 2
mysql> SELECT ABS(-32);
        -> 32
```

This function is safe to use with BIGINT values.

- ACOS(*X*)

Returns the arc cosine of *X*, that is, the value whose cosine is *X*. Returns NULL if *X* is not in the range −1 to 1.

```
mysql> SELECT ACOS(1);
        -> 0.000000
mysql> SELECT ACOS(1.0001);
        -> NULL
mysql> SELECT ACOS(0);
        -> 1.570796
```

- ASIN(*X*)

Returns the arc sine of *X*, that is, the value whose sine is *X*. Returns NULL if *X* is not in the range −1 to 1.

```
mysql> SELECT ASIN(0.2);
        -> 0.201358
mysql> SELECT ASIN('foo');
        -> 0.000000
```

- ATAN(*X*)

  Returns the arc tangent of *X*, that is, the value whose tangent is *X*.

  ```
  mysql> SELECT ATAN(2);
          -> 1.107149
  mysql> SELECT ATAN(-2);
          -> -1.107149
  ```

- ATAN(*Y*,*X*), ATAN2(*Y*,*X*)

  Returns the arc tangent of the two variables *X* and *Y*. It is similar to calculating the arc tangent of *Y* / *X*, except that the signs of both arguments are used to determine the quadrant of the result.

  ```
  mysql> SELECT ATAN(-2,2);
          -> -0.785398
  mysql> SELECT ATAN2(PI(),0);
          -> 1.570796
  ```

- CEILING(*X*), CEIL(*X*)

  Returns the smallest integer value not less than *X*.

  ```
  mysql> SELECT CEILING(1.23);
          -> 2
  mysql> SELECT CEIL(-1.23);
          -> -1
  ```

  Note that the return value is converted to a BIGINT!

  The CEIL() alias was added in MySQL 4.0.6.

- COS(*X*)

  Returns the cosine of *X*, where *X* is given in radians.

  ```
  mysql> SELECT COS(PI());
          -> -1.000000
  ```

- COT(*X*)

  Returns the cotangent of *X*.

  ```
  mysql> SELECT COT(12);
          -> -1.57267341
  mysql> SELECT COT(0);
          -> NULL
  ```

- CRC32(*expr*)

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected be a string and is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
        -> 3259397556
```

`CRC32()` is available as of MySQL 4.1.0.

- `DEGREES(X)`

  Returns the argument X, converted from radians to degrees.

  ```
  mysql> SELECT DEGREES(PI());
          -> 180.000000
  ```

- `EXP(X)`

  Returns the value of e (the base of natural logarithms) raised to the power of X.

  ```
  mysql> SELECT EXP(2);
          -> 7.389056
  mysql> SELECT EXP(-2);
          -> 0.135335
  ```

- `FLOOR(X)`

  Returns the largest integer value not greater than X.

  ```
  mysql> SELECT FLOOR(1.23);
          -> 1
  mysql> SELECT FLOOR(-1.23);
          -> -2
  ```

  Note that the return value is converted to a `BIGINT`!

- `LN(X)`

  Returns the natural logarithm of X.

  ```
  mysql> SELECT LN(2);
          -> 0.693147
  mysql> SELECT LN(-2);
          -> NULL
  ```

  This function was added in MySQL 4.0.3. It is synonymous with `LOG(X)` in MySQL.

- `LOG(X),LOG(B,X)`

  If called with one parameter, this function returns the natural logarithm of X.

  ```
  mysql> SELECT LOG(2);
          -> 0.693147
  mysql> SELECT LOG(-2);
          -> NULL
  ```

If called with two parameters, this function returns the logarithm of *X* for an arbitrary base *B*.

```
mysql> SELECT LOG(2,65536);
        -> 16.000000
mysql> SELECT LOG(1,100);
        -> NULL
```

The arbitrary base option was added in MySQL 4.0.3. `LOG(B,X)` is equivalent to `LOG(X)/LOG(B)`.

- `LOG2(X)`

  Returns the base-2 logarithm of *X*.

```
mysql> SELECT LOG2(65536);
        -> 16.000000
mysql> SELECT LOG2(-100);
        -> NULL
```

`LOG2()` is useful for finding out how many bits a number would require for storage. This function was added in MySQL 4.0.3. In earlier versions, you can use `LOG(X)/LOG(2)` instead.

- `LOG10(X)`

  Returns the base-10 logarithm of *X*.

```
mysql> SELECT LOG10(2);
        -> 0.301030
mysql> SELECT LOG10(100);
        -> 2.000000
mysql> SELECT LOG10(-100);
        -> NULL
```

- `MOD(N,M)`, `N % M`, `N MOD M`

  Modulo operation. Returns the remainder of *N* divided by *M*.

```
mysql> SELECT MOD(234, 10);
        -> 4
mysql> SELECT 253 % 7;
        -> 1
mysql> SELECT MOD(29,9);
        -> 2
mysql> SELECT 29 MOD 9;
        -> 2
```

This function is safe to use with `BIGINT` values. The *N* `MOD` *M* syntax works only as of MySQL 4.1.

As of MySQL 4.1.7, `MOD()` works on values with a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5,3);
        -> 1.5
```

Before MySQL 4.1.7, `MOD()` rounds arguments with a fractional value to integers and returns an integer result:

```
mysql> SELECT MOD(34.5,3);
        -> 2
```

-

  `PI()`

  Returns the value of PI. The default number of decimals displayed is five, but MySQL internally uses the full double-precision value for PI.

```
mysql> SELECT PI();
        -> 3.141593
mysql> SELECT PI()+0.000000000000000000;
        -> 3.141592653589793116
```

-

  `POW(X,Y),POWER(X,Y)`

  Returns the value of X raised to the power of Y.

```
mysql> SELECT POW(2,2);
        -> 4.000000
mysql> SELECT POW(2,-2);
        -> 0.250000
```

-

  `RADIANS(X)`

  Returns the argument X, converted from degrees to radians.

```
mysql> SELECT RADIANS(90);
        -> 1.570796
```

-

  `RAND(),RAND(N)`

  Returns a random floating-point value in the range from `0` to `1.0`. If an integer argument N is specified, it is used as the seed value (producing a repeatable sequence).

```
mysql> SELECT RAND();
        -> 0.9233482386203
mysql> SELECT RAND(20);
        -> 0.15888261251047
mysql> SELECT RAND(20);
        -> 0.15888261251047
mysql> SELECT RAND();
        -> 0.63553050033332
mysql> SELECT RAND();
        -> 0.70100469486881
```

You can't use a column with `RAND()` values in an `ORDER BY` clause, because `ORDER BY` would evaluate the column multiple times. As of MySQL 3.23, you can retrieve rows in random order like this:

```
mysql> SELECT * FROM tbl_name ORDER BY RAND();
```

`ORDER BY RAND()` combined with `LIMIT` is useful for selecting a random sample of a set of rows:

```
mysql> SELECT * FROM table1, table2 WHERE a=b AND c<d
    -> ORDER BY RAND() LIMIT 1000;
```

Note that RAND() in a WHERE clause is re-evaluated every time the WHERE is executed.

RAND() is not meant to be a perfect random generator, but instead a fast way to generate ad hoc random numbers that is portable between platforms for the same MySQL version.

- ROUND(*X*),ROUND(*X*,*D*)

  Returns the argument *X*, rounded to the nearest integer. With two arguments, returns *X* rounded to *D* decimals. *D* can be negative to round *D* digits left of the decimal point of the value *X*.

  ```
  mysql> SELECT ROUND(-1.23);
          -> -1
  mysql> SELECT ROUND(-1.58);
          -> -2
  mysql> SELECT ROUND(1.58);
          -> 2
  mysql> SELECT ROUND(1.298, 1);
          -> 1.3
  mysql> SELECT ROUND(1.298, 0);
          -> 1
  mysql> SELECT ROUND(23.298, -1);
          -> 20
  ```

  The return type is the same type as that of the first argument (assuming it's integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimals).

  Before MySQL 5.0.3, the behavior of ROUND() when the argument is halfway between two integers depends on the C library implementation. Different implementations round to the nearest even number, always up, always down, or always toward zero. If you need one kind of rounding, you should use a well-defined function such as TRUNCATE() or FLOOR() instead.

  As of MySQL 5.0.3, ROUND() uses the precision math library for exact-value arguments when the first argument is a decimal value:

  - For exact-value numbers, ROUND() uses the "round half up" rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.

  - For approximate-value numbers, the result depends on the C library. On many systems, this means that ROUND() uses the "round to nearest even" rule: A value with any fractional part is rounded to the nearest even integer.

  The following example shows how rounding differs for exact and approximate values:

  ```
  mysql> SELECT ROUND(2.5), ROUND(25E-1);
  +------------+--------------+
  | ROUND(2.5) | ROUND(25E-1) |
  +------------+--------------+
  | 3          |            2 |
  +------------+--------------+
  ```

  For more information, see Chapter 22, *Precision Math*.

- SIGN(*X*)

  Returns the sign of the argument as -1, 0, or 1, depending on whether *X* is negative, zero, or positive.

  ```
  mysql> SELECT SIGN(-32);
  ```

```
          -> -1
mysql> SELECT SIGN(0);
          -> 0
mysql> SELECT SIGN(234);
          -> 1
```

-
  `SIN(X)`

  Returns the sine of *X*, where *X* is given in radians.

  ```
  mysql> SELECT SIN(PI());
          -> 0.000000
  ```

-
  `SQRT(X)`

  Returns the non-negative square root of *X*.

  ```
  mysql> SELECT SQRT(4);
          -> 2.000000
  mysql> SELECT SQRT(20);
          -> 4.472136
  ```

-
  `TAN(X)`

  Returns the tangent of *X*, where *X* is given in radians.

  ```
  mysql> SELECT TAN(PI()+1);
          -> 1.557408
  ```

-
  `TRUNCATE(X,D)`

  Returns the number *X*, truncated to *D* decimals. If *D* is 0, the result has no decimal point or fractional part. *D* can be negative to truncate (make zero) *D* digits left of the decimal point of the value *X*.

  ```
  mysql> SELECT TRUNCATE(1.223,1);
          -> 1.2
  mysql> SELECT TRUNCATE(1.999,1);
          -> 1.9
  mysql> SELECT TRUNCATE(1.999,0);
          -> 1
  mysql> SELECT TRUNCATE(-1.999,1);
          -> -1.9
  mysql> SELECT TRUNCATE(122,-2);
          -> 100
  ```

  Starting from MySQL 3.23.51, all numbers are rounded toward zero.

  Note that decimal numbers are normally not stored as exact numbers in computers, but as double-precision values, so you may be surprised by the following result:

  ```
  mysql> SELECT TRUNCATE(10.28*100,0);
          -> 1027
  ```

  This happens because `10.28` is actually stored as something like `10.2799999999999999`.

12.5. Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See Section 11.3, "Date and Time Types" for a description of the range of values each date and time type has and the valid formats in which values may be specified.

Here is an example that uses date functions. The following query selects all records with a `date_col` value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
    -> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

Note that the query also selects records with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW()` within a single query always produce the same result. This principle also applies to `CURDATE()`, `CURTIME()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and to any of their synonyms.

Beginning with MySQL 4.1.3, the `CURRENT_TIMESTAMP()`, `CURRENT_TIME()`, `CURRENT_DATE()`, and `FROM_UNIXTIME()` functions return values in the connection's current time zone, which is available as the value of the `time_zone` system variable. Also, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the current time zone. See Section 5.9.8, "MySQL Server Time Zone Support".

The return value ranges in the following function descriptions apply for complete dates. If a date is a "zero" value or an incomplete date such as `'2001-11-00'`, functions that extract a part of a date may return 0. For example, `DAYOFMONTH('2001-11-00')` returns 0.

- `ADDDATE(date,INTERVAL expr type)`, `ADDDATE(expr,days)`

  When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL` argument, see the discussion for `DATE_ADD()`.

  ```
  mysql> SELECT DATE_ADD('1998-01-02', INTERVAL 31 DAY);
          -> '1998-02-02'
  mysql> SELECT ADDDATE('1998-01-02', INTERVAL 31 DAY);
          -> '1998-02-02'
  ```

  As of MySQL 4.1.1, the second syntax is allowed, where `expr` is a date or datetime expression and `days` is the number of days to be added to `expr`.

  ```
  mysql> SELECT ADDDATE('1998-01-02', 31);
          -> '1998-02-02'
  ```

-

  `ADDTIME(expr,expr2)`

  `ADDTIME()` adds `expr2` to `expr` and returns the result. `expr` is a time or datetime expression, and `expr2` is a time expression.

  ```
  mysql> SELECT ADDTIME('1997-12-31 23:59:59.999999',
      ->                 '1 1:1:1.000002');
          -> '1998-01-02 01:01:01.000001'
  mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
          -> '03:00:01.999997'
  ```

ADDTIME() was added in MySQL 4.1.1.

- CONVERT_TZ(*dt*,*from_tz*,*to_tz*)

  CONVERT_TZ() converts a datetime value *dt* from time zone given by *from_tz* to the time zone given by *to_tz* and returns the resulting value. Time zones may be specified as described in Section 5.9.8, "MySQL Server Time Zone Support". This function returns NULL if the arguments are invalid.

  If the value falls out of the supported range of the TIMESTAMP type when converted fom *from_tz* to UTC, no conversion occurs. The TIMESTAMP range is described at Section 11.1.2, "Overview of Date and Time Types".

  ```
  mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','GMT','MET');
          -> '2004-01-01 13:00:00'
  mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','+00:00','-07:00');
          -> '2004-01-01 05:00:00'
  ```

  To use named time zones such as 'MET' or 'Europe/Moscow', the time zone tables must be properly set up. See Section 5.9.8, "MySQL Server Time Zone Support" for instructions.

  CONVERT_TZ() was added in MySQL 4.1.3.

- CURDATE()

  Returns the current date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

  ```
  mysql> SELECT CURDATE();
          -> '1997-12-15'
  mysql> SELECT CURDATE() + 0;
          -> 19971215
  ```

- CURRENT_DATE , CURRENT_DATE()

  CURRENT_DATE and CURRENT_DATE() are synonyms for CURDATE().

- CURTIME()

  Returns the current time as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context.

  ```
  mysql> SELECT CURTIME();
          -> '23:50:26'
  mysql> SELECT CURTIME() + 0;
          -> 235026
  ```

- CURRENT_TIME , CURRENT_TIME()

  CURRENT_TIME and CURRENT_TIME() are synonyms for CURTIME().

- CURRENT_TIMESTAMP , CURRENT_TIMESTAMP()

  CURRENT_TIMESTAMP and CURRENT_TIMESTAMP() are synonyms for NOW().

-

DATE(`expr`)

Extracts the date part of the date or datetime expression `expr`.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
        -> '2003-12-31'
```

DATE() is available as of MySQL 4.1.1.

•

DATEDIFF(`expr`,`expr2`)

DATEDIFF() returns the number of days between the start date `expr` and the end date `expr2`. `expr` and `expr2` are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('1997-12-31 23:59:59','1997-12-30');
        -> 1
mysql> SELECT DATEDIFF('1997-11-30 23:59:59','1997-12-31');
        -> -31
```

DATEDIFF() was added in MySQL 4.1.1.

•

DATE_ADD(`date`,INTERVAL `expr` `type`) , DATE_SUB(`date`,INTERVAL `expr` `type`)

These functions perform date arithmetic. `date` is a DATETIME or DATE value specifying the starting date. `expr` is an expression specifying the interval value to be added or subtracted from the starting date. `expr` is a string; it may start with a '-' for negative intervals. `type` is a keyword indicating how the expression should be interpreted.

The INTERVAL keyword and the `type` specifier are not case sensitive.

The following table shows how the `type` and `expr` arguments are related:

`type` Value	Expected `expr` Format	Version
MICROSECOND	MICROSECONDS	4.1.1
SECOND	SECONDS	Pre-4.1
MINUTE	MINUTES	Pre-4.1
HOUR	HOURS	Pre-4.1
DAY	DAYS	Pre-4.1
WEEK	WEEKS	5.0.0
MONTH	MONTHS	Pre-4.1
QUARTER	QUARTERS	5.0.0
YEAR	YEARS	Pre-4.1
SECOND_MICROSECOND	'SECONDS.MICROSECONDS'	4.1.1
MINUTE_MICROSECOND	'MINUTES.MICROSECONDS'	4.1.1
MINUTE_SECOND	'MINUTES:SECONDS'	4.1.1
HOUR_MICROSECOND	'HOURS.MICROSECONDS'	4.1.1
HOUR_SECOND	'HOURS:MINUTES:SECONDS'	4.1.1
HOUR_MINUTE	'HOURS:MINUTES'	Pre-4.1
DAY_MICROSECOND	'DAYS.MICROSECONDS'	4.1.1

DAY_SECOND	'DAYS HOURS:MINUTES:SECONDS'	Pre-4.1
DAY_MINUTE	'DAYS HOURS:MINUTES'	Pre-4.1
DAY_HOUR	'DAYS HOURS'	Pre-4.1
YEAR_MONTH	'YEARS-MONTHS'	Pre-4.1

The *type* values DAY_MICROSECOND, HOUR_MICROSECOND, MINUTE_MICROSECOND, SECOND_MICROSECOND, and MICROSECOND are allowed as of MySQL 4.1.1. The values QUARTER and WEEK are allowed as of MySQL 5.0.0.

MySQL allows any punctuation delimiter in the *expr* format. Those shown in the table are the suggested delimiters. If the *date* argument is a DATE value and your calculations involve only YEAR, MONTH, and DAY parts (that is, no time parts), the result is a DATE value. Otherwise, the result is a DATETIME value.

As of MySQL 3.23, INTERVAL *expr type* is allowed on either side of the + operator if the expression on the other side is a date or datetime value. For the – operator, INTERVAL *expr type* is allowed only on the right side, because it makes no sense to subtract a date or datetime value from an interval. (See examples below.)

```
mysql> SELECT '1997-12-31 23:59:59' + INTERVAL 1 SECOND;
        -> '1998-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '1997-12-31';
        -> '1998-01-01'
mysql> SELECT '1998-01-01' - INTERVAL 1 SECOND;
        -> '1997-12-31 23:59:59'
mysql> SELECT DATE_ADD('1997-12-31 23:59:59',
    ->                 INTERVAL 1 SECOND);
        -> '1998-01-01 00:00:00'
mysql> SELECT DATE_ADD('1997-12-31 23:59:59',
    ->                 INTERVAL 1 DAY);
        -> '1998-01-01 23:59:59'
mysql> SELECT DATE_ADD('1997-12-31 23:59:59',
    ->                 INTERVAL '1:1' MINUTE_SECOND);
        -> '1998-01-01 00:01:00'
mysql> SELECT DATE_SUB('1998-01-01 00:00:00',
    ->                 INTERVAL '1 1:1:1' DAY_SECOND);
        -> '1997-12-30 22:58:59'
mysql> SELECT DATE_ADD('1998-01-01 00:00:00',
    ->                 INTERVAL '-1 10' DAY_HOUR);
        -> '1997-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
        -> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
    ->              INTERVAL '1.999999' SECOND_MICROSECOND);
        -> '1993-01-01 00:00:01.000001'
```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the *type* keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a *type* of DAY_SECOND, the value of *expr* is expected to have days, hours, minutes, and seconds parts. If you specify a value like '1:10', MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, '1:10' DAY_SECOND is interpreted in such a way that it is equivalent to '1:10' MINUTE_SECOND. This is analogous to the way that MySQL interprets TIME values as representing elapsed time rather than as time of day.

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```
mysql> SELECT DATE_ADD('1999-01-01', INTERVAL 1 DAY);
        -> '1999-01-02'
```

```
mysql> SELECT DATE_ADD('1999-01-01', INTERVAL 1 HOUR);
        -> '1999-01-01 01:00:00'
```

If you use really malformed dates, the result is NULL. If you add MONTH, YEAR_MONTH, or YEAR and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```
mysql> SELECT DATE_ADD('1998-01-30', INTERVAL 1 MONTH);
        -> '1998-02-28'
```

•

DATE_FORMAT(*date*,*format*)

Formats the *date* value according to the *format* string. The following specifiers may be used in the *format* string:

Specifier	Description
%a	Abbreviated weekday name (Sun..Sat)
%b	Abbreviated month name (Jan..Dec)
%c	Month, numeric (0..12)
%D	Day of the month with English suffix (0th, 1st, 2nd, 3rd, ...)
%d	Day of the month, numeric (00..31)
%e	Day of the month, numeric (0..31)
%f	Microseconds (000000..999999)
%H	Hour (00..23)
%h	Hour (01..12)
%I	Hour (01..12)
%i	Minutes, numeric (00..59)
%j	Day of year (001..366)
%k	Hour (0..23)
%l	Hour (1..12)
%M	Month name (January..December)
%m	Month, numeric (00..12)
%p	AM or PM
%r	Time, 12-hour (hh:mm:ss followed by AM or PM)
%S	Seconds (00..59)
%s	Seconds (00..59)
%T	Time, 24-hour (hh:mm:ss)
%U	Week (00..53), where Sunday is the first day of the week
%u	Week (00..53), where Monday is the first day of the week
%V	Week (01..53), where Sunday is the first day of the week; used with %X
%v	Week (01..53), where Monday is the first day of the week; used with %x
%W	Weekday name (Sunday..Saturday)
%w	Day of the week (0=Sunday..6=Saturday)
%X	Year for the week where Sunday is the first day of the week, numeric, four digits; used with %V
%x	Year for the week, where Monday is the first day of the week, numeric, four digits; used with %v
%Y	Year, numeric, four digits

%y	Year, numeric, two digits
%%	A literal '%'.

All other characters are copied to the result without interpretation.

The `%v`, `%V`, `%x`, and `%X` format specifiers are available as of MySQL 3.23.8. `%f` is available as of MySQL 4.1.1.

As of MySQL 3.23, the '%' character is required before format specifier characters. In earlier versions of MySQL, '%' was optional.

The reason the ranges for the month and day specifiers begin with zero is that MySQL allows incomplete dates such as `'2004-00-00'` to be stored as of MySQL 3.23.

```
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%W %M %Y');
        -> 'Saturday October 1997'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H:%i:%s');
        -> '22:23:00'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
                          '%D %y %a %d %m %b %j');
        -> '4th 97 Sat 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
                          '%H %k %I %r %T %S %w');
        -> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
        -> '1998 52'
```

- DAY(*date*)

  DAY() is a synonym for DAYOFMONTH(). It is available as of MySQL 4.1.1.

- DAYNAME(*date*)

  Returns the name of the weekday for *date*.

  ```
  mysql> SELECT DAYNAME('1998-02-05');
          -> 'Thursday'
  ```

- DAYOFMONTH(*date*)

  Returns the day of the month for *date*, in the range 1 to 31.

  ```
  mysql> SELECT DAYOFMONTH('1998-02-03');
          -> 3
  ```

- DAYOFWEEK(*date*)

  Returns the weekday index for *date* (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

  ```
  mysql> SELECT DAYOFWEEK('1998-02-03');
          -> 3
  ```

- DAYOFYEAR(*date*)

Returns the day of the year for `date`, in the range `1` to `366`.

```
mysql> SELECT DAYOFYEAR('1998-02-03');
        -> 34
```

-
  ```
  EXTRACT(type FROM date)
  ```

  The `EXTRACT()` function uses the same kinds of interval type specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic.

  ```
  mysql> SELECT EXTRACT(YEAR FROM '1999-07-02');
          -> 1999
  mysql> SELECT EXTRACT(YEAR_MONTH FROM '1999-07-02 01:02:03');
          -> 199907
  mysql> SELECT EXTRACT(DAY_MINUTE FROM '1999-07-02 01:02:03');
          -> 20102
  mysql> SELECT EXTRACT(MICROSECOND
      ->                  FROM '2003-01-02 10:30:00.00123');
          -> 123
  ```

  `EXTRACT()` was added in MySQL 3.23.0.

-
  ```
  FROM_DAYS(N)
  ```

  Given a daynumber *N*, returns a `DATE` value.

  ```
  mysql> SELECT FROM_DAYS(729669);
          -> '1997-10-07'
  ```

  Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See Section 12.6, "What Calendar Is Used By MySQL?".

-
  ```
  FROM_UNIXTIME(unix_timestamp)                              ,
  FROM_UNIXTIME(unix_timestamp,format)
  ```

  Returns a representation of the `unix_timestamp` argument as a value in `'YYYY-MM-DD HH:MM:SS'` or `YYYYMMDDHHMMSS` format, depending on whether the function is used in a string or numeric context.

  ```
  mysql> SELECT FROM_UNIXTIME(875996580);
          -> '1997-10-04 22:23:00'
  mysql> SELECT FROM_UNIXTIME(875996580) + 0;
          -> 19971004222300
  ```

  If `format` is given, the result is formatted according to the `format` string. `format` may contain the same specifiers as those listed in the entry for the `DATE_FORMAT()` function.

  ```
  mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(),
      ->                     '%Y %D %M %h:%i:%s %x');
          -> '2003 6th August 06:22:58 2003'
  ```

-
  ```
  GET_FORMAT(DATE|TIME|DATETIME,
  'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL')
  ```

  Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and

the STR_TO_DATE() functions.

The three possible values for the first argument and the five possible values for the second argument result in 15 possible format strings (for the specifiers used, see the table in the DATE_FORMAT() function description).

Function Call	Result
GET_FORMAT(DATE,'USA')	'%m.%d.%Y'
GET_FORMAT(DATE,'JIS')	'%Y-%m-%d'
GET_FORMAT(DATE,'ISO')	'%Y-%m-%d'
GET_FORMAT(DATE,'EUR')	'%d.%m.%Y'
GET_FORMAT(DATE,'INTERNAL')	'%Y%m%d'
GET_FORMAT(DATETIME,'USA')	'%Y-%m-%d-%H.%i.%s'
GET_FORMAT(DATETIME,'JIS')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME,'ISO')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME,'EUR')	'%Y-%m-%d-%H.%i.%s'
GET_FORMAT(DATETIME,'INTERNAL')	'%Y%m%d%H%i%s'
GET_FORMAT(TIME,'USA')	'%h:%i:%s %p'
GET_FORMAT(TIME,'JIS')	'%H:%i:%s'
GET_FORMAT(TIME,'ISO')	'%H:%i:%s'
GET_FORMAT(TIME,'EUR')	'%H.%i.%S'
GET_FORMAT(TIME,'INTERNAL')	'%H%i%s'

ISO format is ISO 9075, not ISO 8601.

As of MySQL 4.1.4, TIMESTAMP can also be used; GET_FORMAT() returns the same values as for DATETIME.

```
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
        -> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
        -> 2003-10-31
```

GET_FORMAT() is available as of MySQL 4.1.1. See Section 13.5.3, "SET Syntax".

-

HOUR(time)

Returns the hour for time. The range of the return value is 0 to 23 for time-of-day values.

```
mysql> SELECT HOUR('10:05:03');
        -> 10
```

However, the range of TIME values actually is much larger, so HOUR can return values greater than 23.

```
mysql> SELECT HOUR('272:59:59');
        -> 272
```

-

LAST_DAY(date)

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns NULL if the argument is invalid.

```
mysql> SELECT LAST_DAY('2003-02-05');
        -> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
        -> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
        -> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
        -> NULL
```

LAST_DAY() is available as of MySQL 4.1.1.

- LOCALTIME , LOCALTIME()

  LOCALTIME and LOCALTIME() are synonyms for NOW().

  They were added in MySQL 4.0.6.

- LOCALTIMESTAMP , LOCALTIMESTAMP()

  LOCALTIMESTAMP and LOCALTIMESTAMP() are synonyms for NOW().

  They were added in MySQL 4.0.6.

- MAKEDATE(*year*,*dayofyear*)

  Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is NULL.

  ```
  mysql> SELECT MAKEDATE(2001,31), MAKEDATE(2001,32);
          -> '2001-01-31', '2001-02-01'
  mysql> SELECT MAKEDATE(2001,365), MAKEDATE(2004,365);
          -> '2001-12-31', '2004-12-30'
  mysql> SELECT MAKEDATE(2001,0);
          -> NULL
  ```

  MAKEDATE() is available as of MySQL 4.1.1.

- MAKETIME(*hour*,*minute*,*second*)

  Returns a time value calculated from the *hour*, *minute*, and *second* arguments.

  ```
  mysql> SELECT MAKETIME(12,15,30);
          -> '12:15:30'
  ```

  MAKETIME() is available as of MySQL 4.1.1.

- MICROSECOND(*expr*)

  Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

  ```
  mysql> SELECT MICROSECOND('12:00:00.123456');
          -> 123456
  mysql> SELECT MICROSECOND('1997-12-31 23:59:59.000010');
          -> 10
  ```

  MICROSECOND() is available as of MySQL 4.1.1.

- MINUTE(*time*)

  Returns the minute for *time*, in the range 0 to 59.

  ```
  mysql> SELECT MINUTE('98-02-03 10:05:03');
          -> 5
  ```

- MONTH(*date*)

  Returns the month for *date*, in the range 1 to 12.

  ```
  mysql> SELECT MONTH('1998-02-03');
          -> 2
  ```

- MONTHNAME(*date*)

  Returns the full name of the month for *date*.

  ```
  mysql> SELECT MONTHNAME('1998-02-05');
          -> 'February'
  ```

- NOW()

  Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDH-HMMSS format, depending on whether the function is used in a string or numeric context.

  ```
  mysql> SELECT NOW();
          -> '1997-12-15 23:50:26'
  mysql> SELECT NOW() + 0;
          -> 19971215235026
  ```

  Within a stored routine or trigger, NOW() returns a constant time that indicates the time at which the routine or triggering statement began to execute. This differs from the behavior for SYS-DATE().

- PERIOD_ADD(*P*,*N*)

  Adds *N* months to period *P* (in the format YYMM or YYYYMM). Returns a value in the format YYYYMM. Note that the period argument *P* is *not* a date value.

  ```
  mysql> SELECT PERIOD_ADD(9801,2);
          -> 199803
  ```

- PERIOD_DIFF(*P1*,*P2*)

  Returns the number of months between periods *P1* and *P2*. *P1* and *P2* should be in the format YYMM or YYYYMM. Note that the period arguments *P1* and *P2* are *not* date values.

  ```
  mysql> SELECT PERIOD_DIFF(9802,199703);
          -> 11
  ```

- QUARTER(*date*)

Returns the quarter of the year for *date*, in the range 1 to 4.

```
mysql> SELECT QUARTER('98-04-01');
        -> 2
```

- SECOND(*time*)

Returns the second for *time*, in the range 0 to 59.

```
mysql> SELECT SECOND('10:05:03');
        -> 3
```

- SEC_TO_TIME(*seconds*)

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT SEC_TO_TIME(2378);
        -> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
        -> 3938
```

- STR_TO_DATE(*str,format*)

This is the reverse function of the DATE_FORMAT() function. It takes a string *str* and a format string *format*. STR_TO_DATE() returns a DATETIME value if the format string contains both date and time parts, or a DATE or TIME value if the string contains only date or time parts.

The date, time, or datetime values contained in *str* should be given in the format indicated by *format*. For the specifiers that can be used in *format*, see the table in the DATE_FORMAT() function description. All other characters are just taken verbatim, thus not being interpreted. If *str* contains an illegal date, time, or datetime value, STR_TO_DATE() returns NULL. Starting from MySQL 5.0.3, an illegal value also produces a warning.

```
mysql> SELECT STR_TO_DATE('03.10.2003 09.20',
    ->                     '%d.%m.%Y %H.%i');
        -> '2003-10-03 09:20:00'
mysql> SELECT STR_TO_DATE('10arp', '%carp');
        -> '0000-10-00 00:00:00'
mysql> SELECT STR_TO_DATE('2003-15-10 00:00:00',
    ->                     '%Y-%m-%d %H:%i:%s');
        -> NULL
```

Range checking on the parts of date values is as described in Section 11.3.1, "The DATETIME, DATE, and TIMESTAMP Types". This means, for example, that a date with a day part larger than the number of days in a month is allowable as long as the day part is in the range from 1 to 31. Also, "zero" dates or dates with part values of 0 are allowed.

```
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
        -> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004', '%m/%d/%Y');
        -> '2004-04-31'
```

STR_TO_DATE() is available as of MySQL 4.1.1.

- SUBDATE(`date`,INTERVAL `expr type`),SUBDATE(`expr`,`days`)

When invoked with the INTERVAL form of the second argument, SUBDATE() is a synonym for DATE_SUB(). For information on the INTERVAL argument, see the discussion for DATE_ADD().

```
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
        -> '1997-12-02'
mysql> SELECT SUBDATE('1998-01-02', INTERVAL 31 DAY);
        -> '1997-12-02'
```

As of MySQL 4.1.1, the second syntax is allowed, where `expr` is a date or datetime expression and `days` is the number of days to be subtracted from `expr`.

```
mysql> SELECT SUBDATE('1998-01-02 12:00:00', 31);
        -> '1997-12-02 12:00:00'
```

Note that you can't use format "%X%V" to convert a year-week string to date as a year-week doesn't uniquely identify a year-month if the week crosses a month boundary. If you want to convert a year-week to a date you can do it by also specifying the week day:

```
mysql> select str_to_date('200442 Monday', '%X%V %W');
-> 2004-10-18
```

- SUBTIME(`expr`,`expr2`)

SUBTIME() subtracts `expr2` from `expr` and returns the result. `expr` is a time or datetime expression, and `expr2` is a time expression.

```
mysql> SELECT SUBTIME('1997-12-31 23:59:59.999999',
    ->                 '1 1:1:1.000002');
        -> '1997-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
        -> '-00:59:59.999999'
```

SUBTIME() was added in MySQL 4.1.1.

- SYSDATE()

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHMMSS format, depending on whether the function is used in a string or numeric context.

Within a stored routine or trigger, SYSDATE() returns the time at which it executes, not the time at which the routine or triggering statement began to execute. This differs from the behavior for NOW().

- TIME(`expr`)

Extracts the time part of the time or datetime expression `expr` and returns it as a string.

```
mysql> SELECT TIME('2003-12-31 01:02:03');
        -> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
        -> '01:02:03.000123'
```

TIME() is available as of MySQL 4.1.1.

- TIMEDIFF(*expr,expr2*)

  TIMEDIFF() returns the time between the start time *expr* and the end time *expr2*. *expr* and *expr2* are time or date-and-time expressions, but both must be of the same type.

  ```
  mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
      ->                 '2000:01:01 00:00:00.000001');
          -> '-00:00:00.000001'
  mysql> SELECT TIMEDIFF('1997-12-31 23:59:59.000001',
      ->                 '1997-12-30 01:01:01.000002');
          -> '46:58:57.999999'
  ```

  TIMEDIFF() was added in MySQL 4.1.1.

- TIMESTAMP(*expr*),TIMESTAMP(*expr,expr2*)

  With one argument, returns the date or datetime expression *expr* as a datetime value. With two arguments, adds the time expression *expr2* to the date or datetime expression *expr* and returns a datetime value.

  ```
  mysql> SELECT TIMESTAMP('2003-12-31');
          -> '2003-12-31 00:00:00'
  mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
          -> '2004-01-01 00:00:00'
  ```

  TIMESTAMP() is available as of MySQL 4.1.1.

- TIMESTAMPADD(*interval,int_expr,datetime_expr*)

  Adds the integer expression *int_expr* to the date or datetime expression *datetime_expr*. The unit for *int_expr* is given by the interval argument, which should be one of the following values: FRAC_SECOND, SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER, or YEAR.

  The *interval* value may be specified using one of keywords as shown, or with a prefix of SQL_TSI_. For example, DAY or SQL_TSI_DAY both are legal.

  ```
  mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
          -> '2003-01-02 00:01:00'
  mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
          -> '2003-01-09'
  ```

  TIMESTAMPADD() is available as of MySQL 5.0.0.

- TIMESTAMPDIFF(*interval,datetime_expr1,datetime_expr2*)

  Returns the integer difference between the date or datetime expressions *datetime_expr1* and *datetime_expr2*. The unit for the result is given by the *interval* argument. The legal values for *interval* are the same as those listed in the description of the TIMESTAMPADD() function.

  ```
  mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
          -> 3
  mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
          -> -1
  ```

TIMESTAMPDIFF() is available as of MySQL 5.0.0.

•

TIME_FORMAT(*time*,*format*)

This is used like the DATE_FORMAT() function, but the *format* string may contain only those format specifiers that handle hours, minutes, and seconds. Other specifiers produce a NULL value or 0.

If the *time* value contains an hour part that is greater than 23, the %H and %k hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
        -> '100 100 04 04 4'
```

•

TIME_TO_SEC(*time*)

Returns the *time* argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
        -> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
        -> 2378
```

•

TO_DAYS(*date*)

Given a date *date*, returns a daynumber (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
        -> 728779
mysql> SELECT TO_DAYS('1997-10-07');
        -> 729669
```

TO_DAYS() is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in Section 11.3, "Date and Time Types". For example, '1997-10-07' and '97-10-07' are seen as identical dates:

```
mysql> SELECT TO_DAYS('1997-10-07'), TO_DAYS('97-10-07');
        -> 729669, 729669
```

For other dates before 1582, results from this function are undefined.

•

UNIX_TIMESTAMP(),UNIX_TIMESTAMP(*date*)

If called with no argument, returns a Unix timestamp (seconds since '1970-01-01 00:00:00' GMT) as an unsigned integer. If UNIX_TIMESTAMP() is called with a *date* argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' GMT. *date* may be a DATE string, a DATETIME string, a TIMESTAMP, or a number in the format YYMMDD or YYYYMMDD in local time.

```
mysql> SELECT UNIX_TIMESTAMP();
        -> 882226357
mysql> SELECT UNIX_TIMESTAMP('1997-10-04 22:23:00');
```

```
                    -> 875996580
```

When `UNIX_TIMESTAMP` is used on a `TIMESTAMP` column, the function returns the internal timestamp value directly, with no implicit "string-to-Unix-timestamp" conversion. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns `0`, but please note that only basic range checking is performed (year from `1970` to `2037`, month from `01` to `12`, day from `01` from `31`).

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast the result to signed integers. See Section 12.8, "Cast Functions and Operators".

- `UTC_DATE` , `UTC_DATE()`

  Returns the current UTC date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in a string or numeric context.

  ```
  mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
          -> '2003-08-14', 20030814
  ```

  `UTC_DATE()` is available as of MySQL 4.1.1.

- `UTC_TIME` , `UTC_TIME()`

  Returns the current UTC time as a value in `'HH:MM:SS'` or `HHMMSS` format, depending on whether the function is used in a string or numeric context.

  ```
  mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
          -> '18:07:53', 180753
  ```

  `UTC_TIME()` is available as of MySQL 4.1.1.

- `UTC_TIMESTAMP` , `UTC_TIMESTAMP()`

  Returns the current UTC date and time as a value in `'YYYY-MM-DD HH:MM:SS'` or `YYYYM-MDDHHMMSS` format, depending on whether the function is used in a string or numeric context.

  ```
  mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
          -> '2003-08-14 18:08:04', 20030814180804
  ```

  `UTC_TIMESTAMP()` is available as of MySQL 4.1.1.

- `WEEK(date[,mode])`

  The function returns the week number for `date`. The two-argument form of `WEEK()` allows you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from `0` to `53` or from `1` to `53`. If the `mode` argument is omitted, the value of the `default_week_format` system variable is used (or `0` before MySQL 4.0.14). See Section 5.3.3, "Server System Variables".

  The following table describes how the `mode` argument works:

Mode	First day of week	Range	Week 1 is the first week...
0	Sunday	0-53	with a Sunday in this year
1	Monday	0-53	with more than 3 days this year

2	Sunday	1-53	with a Sunday in this year
3	Monday	1-53	with more than 3 days this year
4	Sunday	0-53	with more than 3 days this year
5	Monday	0-53	with a Monday in this year
6	Sunday	1-53	with more than 3 days this year
7	Monday	1-53	with a Monday in this year

A *mode* value of 3 can be used as of MySQL 4.0.5. Values of 4 and above can be used as of MySQL 4.0.17.

```
mysql> SELECT WEEK('1998-02-20');
        -> 7
mysql> SELECT WEEK('1998-02-20',0);
        -> 7
mysql> SELECT WEEK('1998-02-20',1);
        -> 8
mysql> SELECT WEEK('1998-12-31',1);
        -> 53
```

Note: In MySQL 4.0, WEEK(*date*,0) was changed to match the calendar in the USA. Before that, WEEK() was calculated incorrectly for dates in the USA. (In effect, WEEK(*date*) and WEEK(*date*,0) were incorrect for all cases.)

Note that if a date falls in the last week of the previous year, MySQL returns 0 if you don't use 2, 3, 6, or 7 as the optional mode argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
        -> 2000, 0
```

One might argue that MySQL should return 52 for the WEEK() function, because the given date actually occurs in the 52nd week of 1999. We decided to return 0 instead because we want the function to return "the week number in the given year." This makes use of the WEEK() function reliable when combined with other functions that extract a date part from a date.

If you would prefer the result to be evaluated with respect to the year that contains the first day of the week for the given date, you should use 0, 2, 5, or 7 as the optional mode argument.

```
mysql> SELECT WEEK('2000-01-01',2);
        -> 52
```

Alternatively, use the YEARWEEK() function:

```
mysql> SELECT YEARWEEK('2000-01-01');
        -> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
        -> '52'
```

-

  WEEKDAY(*date*)

  Returns the weekday index for *date* (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('1998-02-03 22:23:00');
        -> 1
mysql> SELECT WEEKDAY('1997-11-05');
        -> 2
```

- WEEKOFYEAR(*date*)

  Returns the calendar week of the date as a number in the range from `1` to `53`. It is a compatibility function that is equivalent to `WEEK(date,3)`.

  ```
  mysql> SELECT WEEKOFYEAR('1998-02-20');
          -> 8
  ```

  `WEEKOFYEAR()` is available as of MySQL 4.1.1.

- YEAR(*date*)

  Returns the year for *date*, in the range `1000` to `9999`.

  ```
  mysql> SELECT YEAR('98-02-03');
          -> 1998
  ```

- YEARWEEK(*date*), YEARWEEK(*date,start*)

  Returns year and week for a date. The *start* argument works exactly like the *start* argument to `WEEK()`. The year in the result may be different from the year in the date argument for the first and the last week of the year.

  ```
  mysql> SELECT YEARWEEK('1987-01-01');
          -> 198653
  ```

  Note that the week number is different from what the `WEEK()` function would return (`0`) for optional arguments `0` or `1`, as `WEEK()` then returns the week in the context of the given year.

  `YEARWEEK()` was added in MySQL 3.23.8.

12.6. What Calendar Is Used By MySQL?

MySQL uses what is known as a **proleptic Gregorian calendar**.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, let's look at the month of October 1582, when the first Julian-to-Gregorian switch occurred:

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
1	2	3	4	15	16	17
18	19	20	21	22	23	24
25	26	27	28	29	30	31

There are no dates between October 4 and October 15. This discontinuity is called the **cutover**. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it wasn't actually in use is called **proleptic**. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL `DATE` or `DATETIME` values must be adjusted to compensate for the difference. It is important to realise that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in

1752, when Wednesday September 2 was followed by Thursday September 14; Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its "October Revolution" occurred in November according to the Gregorian calendar.

12.7. Full-Text Search Functions

-
    ```
    MATCH (col1,col2,...) AGAINST (expr [IN BOOLEAN MODE | WITH
    QUERY EXPANSION])
    ```

    As of MySQL 3.23.23, MySQL has support for full-text indexing and searching. A full-text index in MySQL is an index of type FULLTEXT. FULLTEXT indexes are used with MyISAM tables only and can be created from CHAR, VARCHAR, or TEXT columns at CREATE TABLE time or added later with ALTER TABLE or CREATE INDEX. For large datasets, it is much faster to load your data into a table that has no FULLTEXT index, then create the index with ALTER TABLE (or CREATE INDEX). Loading data into a table that has an existing FULL-TEXT index could be significantly slower.

    Constraints on full-text searching are listed in Section 12.7.3, "Full-Text Restrictions".

Full-text searching is performed with the MATCH() function.

```
mysql> CREATE TABLE articles (
    ->    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    ->    title VARCHAR(200),
    ->    body TEXT,
    ->    FULLTEXT (title,body)
    -> );
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO articles (title,body) VALUES
    -> ('MySQL Tutorial','DBMS stands for DataBase ...'),
    -> ('How To Use MySQL Well','After you went through a ...'),
    -> ('Optimizing MySQL','In this tutorial we will show ...'),
    -> ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
    -> ('MySQL vs. YourSQL','In the following database comparison ...'),
    -> ('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.00 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body) AGAINST ('database');
+----+-------------------+------------------------------------------+
| id | title             | body                                     |
+----+-------------------+------------------------------------------+
|  5 | MySQL vs. YourSQL | In the following database comparison ... |
|  1 | MySQL Tutorial    | DBMS stands for DataBase ...             |
+----+-------------------+------------------------------------------+
2 rows in set (0.00 sec)
```

The MATCH() function performs a natural language search for a string against a text collection. A collection is a set of one or more columns included in a FULLTEXT index. The search string is given as the argument to AGAINST(). For every row in the table, MATCH() returns a relevance value, that is, a similarity measure between the search string and the text in that row in the columns named in the MATCH() list.

By default, the search is performed in case-insensitive fashion. In MySQL 4.1 and up, you can make a full-text search by using a binary collation for the indexed columns. For example, a column that has a character set of latin1 can be assigned a collation of latin1_bin to make it case sensitive for full-text searches.

When MATCH() is used in a WHERE clause, as in the preceding example, the rows returned are automatically sorted with the highest relevance first. Relevance values are non-negative floating-

point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row, the number of unique words in that row, the total number of words in the collection, and the number of documents (rows) that contain a particular word.

For natural-language full-text searches, it is a requirement that the columns named in the `MATCH()` function be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. If you wanted to search the `title` or `body` separately, you would need to create `FULLTEXT` indexes for each column.

It is also possible to perform a boolean search or a search with query expansion. These search types are described in Section 12.7.1, "Boolean Full-Text Searches" and Section 12.7.2, "Full-Text Searches with Query Expansion".

The preceding example is a basic illustration showing how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title,body) AGAINST ('Tutorial')
    -> FROM articles;
+----+-----------------------------------------+
| id | MATCH (title,body) AGAINST ('Tutorial') |
+----+-----------------------------------------+
|  1 |                           0.65545833110809 |
|  2 |                                          0 |
|  3 |                           0.66266459226608 |
|  4 |                                          0 |
|  5 |                                          0 |
|  6 |                                          0 |
+----+-----------------------------------------+
6 rows in set (0.00 sec)
```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, you should specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```
mysql> SELECT id, body, MATCH (title,body) AGAINST
    -> ('Security implications of running MySQL as root') AS score
    -> FROM articles WHERE MATCH (title,body) AGAINST
    -> ('Security implications of running MySQL as root');
+----+-------------------------------------+-----------------+
| id | body                                | score           |
+----+-------------------------------------+-----------------+
|  4 | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
|  6 | When configured properly, MySQL ... | 1.3114095926285 |
+----+-------------------------------------+-----------------+
2 rows in set (0.00 sec)
```

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes (`'`), but not more than one in a row. This means that `aaa'bbb` is regarded as one word, but `aaa''bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; `'aaa'bbb'` would be parsed as `aaa'bbb`.

The `FULLTEXT` parser determines where words start and end by looking for certain delimiters, for example `' '` (the space character), `,` (the comma), and `.` (the period). If words aren't separated by delimiters, like for example Chinese words, the `FULLTEXT` parser cannot determine where a word starts and where it ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index, you'd have to preprocess them so that they are separated by some delimiter (for example, by `' '`).

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is four characters.

- Words in the stopword list are ignored. A stopword is a word such as "the" or "some" that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overwritten by a user-defined list. See Section 12.7.4, "Fine-Tuning MySQL Full-Text Search".

The default minimum word length and stopword list can be changed as described in Section 12.7.4, "Fine-Tuning MySQL Full-Text Search".

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. This way, a word that is present in many documents has a lower weight (and may even have a zero weight), because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are then combined to compute the relevance of the row.

Such a technique works best with large collections (in fact, it was carefully tuned this way). For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results. For example, although the word "MySQL" is present in every row of the `articles` table, a search for the word produces no results:

```
mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body) AGAINST ('MySQL');
Empty set (0.00 sec)
```

The search result is empty because the word "MySQL" is present in at least 50% of the rows. As such, it is effectively treated as a stopword. For large datasets, this is the most desirable behavior---a natural language query should not return every second row from a 1GB table. For small datasets, it may be less desirable.

A word that matches half of rows in a table is less likely to locate relevant documents. In fact, it most likely finds plenty of irrelevant documents. We all know this happens far too often when we are trying to find something on the Internet with a search engine. It is with this reasoning that rows containing the word are assigned a low semantic value for *the particular dataset in which they occur*. A given word may exceed the 50% threshold in one dataset but not another.

The 50% threshold has a significant implication when you first try full-text searching to see how it works: If you create a table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results. Be sure to insert at least three rows, and preferably many more. Users who need to bypass the 50% limitation can use the boolean search mode, see Section 12.7.1, "Boolean Full-Text Searches".

12.7.1. Boolean Full-Text Searches

As of Version 4.0.1, MySQL can also perform boolean full-text searches using the `IN BOOLEAN MODE` modifier.

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
    -> AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
+----+-----------------------+-------------------------------------+
| id | title                 | body                                |
+----+-----------------------+-------------------------------------+
|  1 | MySQL Tutorial        | DBMS stands for DataBase ...        |
|  2 | How To Use MySQL Well | After you went through a ...        |
|  3 | Optimizing MySQL      | In this tutorial we will show ...   |
|  4 | 1001 MySQL Tricks     | 1. Never run mysqld as root. 2. ... |
|  6 | MySQL Security        | When configured properly, MySQL ... |
+----+-----------------------+-------------------------------------+
```

This query retrieves all the rows that contain the word "MySQL" but that do *not* contain the word "YourSQL".

Boolean full-text searches have these characteristics:

- They do not use the 50% threshold.

- They do not automatically sort rows in order of decreasing relevance. You can see this from the preceding query result: The row with the highest relevance is the one that contains "MySQL" twice, but it is listed last, not first.

- They can work even without a FULLTEXT index, although this would be *slow*.

- The minimum and maximum word length full-text parameters apply.

- The stopword list applies.

The boolean full-text search capability supports the following operators:

- +

  A leading plus sign indicates that this word *must be* present in every row returned.

- –

  A leading minus sign indicates that this word *must not be* present in any row returned.

- (no operator)

  By default (when neither + nor – is specified) the word is optional, but the rows that contain it are rated higher. This mimics the behavior of MATCH() ... AGAINST() without the IN BOOLEAN MODE modifier.

- > <

  These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The > operator increases the contribution and the < operator decreases it. See the example below.

- ( )

  Parentheses are used to group words into subexpressions. Parenthesized groups can be nested.

- ~

  A leading tilde acts as a negation operator, causing the word's contribution to the row relevance to be negative. It's useful for marking noise words. A row that contains such a word is rated lower than others, but is not excluded altogether, as it would be with the – operator.

- *

  An asterisk is the truncation operator. Unlike the other operators, it should be *appended* to the word.

- "

  A phrase that is enclosed within double quote ('"') characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words, performs a search in the FULLTEXT index for the words. Before MySQL 5.0.3, the engine then performs a substring search for the phrase in the records that are found, so the match must include non-word

characters in the phrase. As of MySQL 5.0.3, non-word characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"` as of MySQL 5.0.3, but not before.

If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`

  Find rows that contain at least one of the two words.

- `'+apple +juice'`

  Find rows that contain both words.

- `'+apple macintosh'`

  Find rows that contain the word "apple", but rank rows higher if they also contain "macintosh".

- `'+apple -macintosh'`

  Find rows that contain the word "apple" but not "macintosh".

- `'+apple +(>turnover <strudel)'`

  Find rows that contain the words "apple" and "turnover", or "apple" and "strudel" (in any order), but rank "apple turnover" higher than "apple strudel".

- `'apple*'`

  Find rows that contain words such as "apple", "apples", "applesauce", or "applet".

- `'"some words"'`

  Find rows that contain the exact phrase "some words" (for example, rows that contain "some words of wisdom" but not "some noise words"). Note that the '"' characters that surround the phrase are operator characters that delimit the phrase. They are not the quotes that surround the search string itself.

12.7.2. Full-Text Searches with Query Expansion

As of MySQL 4.1.1, full-text search supports query expansion (in particular, its variant "blind query expansion"). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine usually lacks. For example, a user searching for "database" may really mean that "MySQL", "Oracle", "DB2", and "RDBMS" all are phrases that should match "databases" and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few top found documents from the first search. Thus, if one of these documents contains the word "databases" and the word "MySQL", the second search finds the documents that contain the word "MySQL" even if they do not contain the word "database". The following example shows this difference:

```
mysql> SELECT * FROM articles
```

```
    -> WHERE MATCH (title,body) AGAINST ('database');
+----+-------------------+------------------------------------------+
| id | title             | body                                     |
+----+-------------------+------------------------------------------+
|  5 | MySQL vs. YourSQL | In the following database comparison ... |
|  1 | MySQL Tutorial    | DBMS stands for DataBase ...             |
+----+-------------------+------------------------------------------+
2 rows in set (0.00 sec)

mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('database' WITH QUERY EXPANSION);
+----+-------------------+------------------------------------------+
| id | title             | body                                     |
+----+-------------------+------------------------------------------+
|  1 | MySQL Tutorial    | DBMS stands for DataBase ...             |
|  5 | MySQL vs. YourSQL | In the following database comparison ... |
|  3 | Optimizing MySQL  | In this tutorial we will show ...        |
+----+-------------------+------------------------------------------+
3 rows in set (0.00 sec)
```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell "Maigret". A search for "Megre and the reluctant witnesses" finds only "Maigret and the Reluctant Witnesses" without query expansion. A search with query expansion finds all books with the word "Maigret" on the second pass.

Note: Because blind query expansion tends to increase noise significantly by returning non-relevant documents, it's only meaningful to use when a search phrase is rather short.

12.7.3. Full-Text Restrictions

- Full-text searches are supported for `MyISAM` tables only.

- As of MySQL 4.1.1, full-text searches can be used with most multi-byte character sets. The exception is that for Unicode, the `utf8` character set can be used, but not the `ucs2` character set.

- Languages such as Chinese, Japanese, and so forth don't have word delimiters. You should be aware that the `FULLTEXT` parser cannot determine where a word starts and where it ends in these languages. Implications and workarounds are described in Section 12.7, "Full-Text Search Functions".

- As of MySQL 4.1, the use of multiple character sets within a single table is supported. However, all columns in a `FULLTEXT` index must have the same character set and collation.

- The `MATCH()` column list must exactly match the column list in some `FULLTEXT` index definition for the table, unless this `MATCH()` is `IN BOOLEAN MODE`.

- The argument to `AGAINST()` must be a constant string.

12.7.4. Fine-Tuning MySQL Full-Text Search

The MySQL full-text search capability has few user-tunable parameters yet, although adding more is very high on the TODO. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See Section 2.8, "MySQL Installation Using a Source Distribution".

Note that full-text search was carefully tuned for the best searching effectiveness. Modifying the default behavior, in most cases, makes the search results worse. Do not alter the MySQL sources unless you know what you are doing!

Most full-text variables described in the following items must be set at server startup time. For these variables, a server restart is required to change them and you cannot modify them dynamically while

the server is running.

Some variable changes require that you rebuild the FULLTEXT indexes in your tables. Instructions for doing this are given at the end of this section.

- The minimum and maximum length of words to be indexed is defined by the ft_min_word_len and ft_max_word_len system variables (available as of MySQL 4.0.0). See Section 5.3.3, "Server System Variables". The default minimum value is four characters. The default maximum depends on your version of MySQL. If you change either value, you must rebuild your FULLTEXT indexes. For example, if you want three-character words to be searchable, you can set the ft_min_word_len variable by putting the following lines in an option file:

```
[mysqld]
ft_min_word_len=3
```

  Then restart the server and rebuild your FULLTEXT indexes. Also note particularly the remarks regarding myisamchk in the instructions following this list.

- To override the default stopword list, set the ft_stopword_file system variable (available as of MySQL 4.0.10). See Section 5.3.3, "Server System Variables". The variable value should be the pathname of the file containing the stopword list, or the empty string to disable stopword filtering. After changing the value of this variable or the contents of the stopword file, rebuild your FULLTEXT indexes.

  The stopword list is free-form, that is, you may use any non-alphanumeric character such as newline, space, or comma to separate stopwords. Exceptions are the underscore character (_) and a single apostrophe (') which are treated as part of a word. The character set of the stopword list is the server's default character set; see Section 10.3.1, "Server Character Set and Collation".

- The 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in myisam/ftdefs.h:

```
#define GWS_IN_USE GWS_PROB
```

  Change the line to this:

```
#define GWS_IN_USE GWS_FREQ
```

  Then recompile MySQL. There is no need to rebuild the indexes in this case. **Note**: By doing this you *severely* decrease MySQL's ability to provide adequate relevance values for the MATCH() function. If you really need to search for such common words, it would be better to search using IN BOOLEAN MODE instead, which does not observe the 50% threshold.

- To change the operators used for boolean full-text searches, set the ft_boolean_syntax system variable (available as of MySQL 4.0.1). The variable also can be changed while the server is running, but you must have the SUPER privilege to do so. No index rebuilding is necessary. Section 5.3.3, "Server System Variables" describes the rules that define how to set this variable.

If you modify full-text variables that affect indexing (ft_min_word_len, ft_max_word_len, or ft_stopword_file), or if you change the stopword file itself, you must rebuild your FULL-TEXT indexes after making the changes and restarting the server. To rebuild the indexes in this case, it's sufficient to do a QUICK repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

With regard specifically to using the IN BOOLEAN MODE capability, if you upgrade from MySQL

3.23 to 4.0 or later, it's necessary to replace the index header as well. To do this, do a USE_FRM repair operation:

```
mysql> REPAIR TABLE tbl_name USE_FRM;
```

This is necessary because boolean full-text searches require a flag in the index header that was not present in MySQL 3.23, and that is not added if you do only a QUICK repair. If you attempt a boolean full-text search without rebuilding the indexes this way, the search returns incorrect results.

Note that if you use myisamchk to perform an operation that modifies table indexes (such as repair or analyze), the FULLTEXT indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in MyISAM index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same ft_min_word_len, ft_max_word_len, and ft_stopword_file values to myisamchk that you use for mysqld. For example, if you have set the minimum word length to 3, you can repair a table with myisamchk like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that myisamchk and the server use the same values for full-text parameters, you can place each one in both the [mysqld] and [myisamchk] sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using myisamchk is to use the REPAIR TABLE, ANALYZE TABLE, OPTIMIZE TABLE, or ALTER TABLE. These statements are performed by the server, which knows the proper full-text parameter values to use.

12.7.5. Full-Text Search TODO

- Improved performance for all FULLTEXT operations.

- Proximity operators.

- Support for "always-index words." These could be any strings the user wants to treat as words, such as "C++", "AS/400", or "TCP/IP".

- Support for full-text search in MERGE tables.

- Support for the ucs2 character set.

- Make the stopword list dependent on the language of the dataset.

- Stemming

- Generic user-suppliable UDF preparser.

- Make the model more flexible (by adding some adjustable parameters to FULLTEXT in CREATE TABLE and ALTER TABLE statements).

12.8. Cast Functions and Operators

- `BINARY`

  The `BINARY` operator casts the string following it to a binary string. This is an easy way to force a column comparison to be done byte by byte rather than character by character. This causes the comparison to be case sensitive even if the column isn't defined as `BINARY` or `BLOB`. `BINARY` also causes trailing spaces to be significant.

  ```
  mysql> SELECT 'a' = 'A';
          -> 1
  mysql> SELECT BINARY 'a' = 'A';
          -> 0
  mysql> SELECT 'a' = 'a ';
          -> 1
  mysql> SELECT BINARY 'a' = 'a ';
          -> 0
  ```

  `BINARY` affects the entire comparison; it can be given before either operand with the same result.

  `BINARY` was added in MySQL 3.23.0. As of MySQL 4.0.2, `BINARY str` is a shorthand for `CAST(str AS BINARY)`.

  Note that in some contexts, if you cast an indexed column to `BINARY`, MySQL is not able to use the index efficiently.

  If you want to compare a `BLOB` value or other binary string in case-insensitive fashion, you can do so as follows:

  - Before MySQL 4.1.1, use the `UPPER()` function to convert the binary string to uppercase before performing the comparison:

    ```
    SELECT 'A' LIKE UPPER(blob_col) FROM tbl_name;
    ```

    If the comparison value is lowercase, convert the string value using `LOWER()` instead.

  - For MySQL 4.1.1 and up, binary strings have no character set, and thus no concept of letter-case. To perform a case-insensitive comparison, use the `CONVERT()` function to convert the string value to a character set that is not case sensitive. The result is a non-binary string, so the `LIKE` operation is not case sensitive:

    ```
    SELECT 'A' LIKE CONVERT(blob_col USING latin1) FROM tbl_name;
    ```

    To use a different character set, substitute its name for `latin1` in the preceding statement.

  `CONVERT()` can be used more generally for comparing strings that are represented in different character sets.

-
  `CAST(expr AS type)` , `CONVERT(expr,type)` , `CONVERT(expr USING transcoding_name)`

  The `CAST()` and `CONVERT()` functions can be used to take a value of one type and produce a value of another type.

  The `type` can be one of the following values:

  - `BINARY`

  - `CHAR`

  - `DATE`

- DATETIME

- DECIMAL

- SIGNED [INTEGER]

- TIME

- UNSIGNED [INTEGER]

BINARY produces a binary string. See the entry for the BINARY operator in this section for a description of how this affects comparisons.

CAST() and CONVERT() are available as of MySQL 4.0.2. The CHAR conversion type is available as of 4.0.6. The USING form of CONVERT() is available as of 4.1.0.

The DECIMAL type is available as of MySQL 5.0.8.

CAST() and CONVERT(... USING ...) are standard SQL syntax. The non-USING form of CONVERT() is ODBC syntax.

CONVERT() with USING is used to convert data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the server's default character set to the corresponding string in the utf8 character set:

```
SELECT CONVERT('abc' USING utf8);
```

The cast functions are useful when you want to create a column with a specific type in a CREATE ... SELECT statement:

```
CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE);
```

The functions also can be useful for sorting ENUM columns in lexical order. Normally sorting of ENUM columns occurs using the internal numeric values. Casting the values to CHAR results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

CAST(str AS BINARY) is the same thing as BINARY str. CAST(expr AS CHAR) treats the expression as a string with the default character set.

Note: In MySQL 4.0, a CAST() to DATE, DATETIME, or TIME only marks the column to be a specific type but doesn't change the value of the column.

As of MySQL 4.1.0, the value is converted to the correct column type when it's sent to the user (this is a feature of how the new protocol in 4.1 sends date information to the client):

```
mysql> SELECT CAST(NOW() AS DATE);
        -> 2003-05-26
```

As of MySQL 4.1.1, CAST() also changes the result if you use it as part of a more complex expression such as CONCAT('Date: ',CAST(NOW() AS DATE)).

You should not use CAST() to extract data in different formats but instead use string functions like LEFT() or EXTRACT(). See Section 12.5, "Date and Time Functions".

To cast a string to a numeric value in numeric context, you don't normally have to do anything. Just use the string value as though it were a number:

```
mysql> SELECT 1+'1';
        -> 2
```

If you use a number in string context, the number automatically is converted to a `BINARY` string.

```
mysql> SELECT CONCAT('hello you ',2);
        -> 'hello you 2'
```

MySQL supports arithmetic with both signed and unsigned 64-bit values. If you are using numeric operators (such as +) and one of the operands is an unsigned integer, the result is unsigned. You can override this by using the `SIGNED` and `UNSIGNED` cast operators to cast the operation to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT CAST(1-2 AS UNSIGNED)
        -> 18446744073709551615
mysql> SELECT CAST(CAST(1-2 AS UNSIGNED) AS SIGNED);
        -> -1
```

Note that if either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
        -> -1.0
```

If you are using a string in an arithmetic operation, this is converted to a floating-point number.

The handing of unsigned values was changed in MySQL 4.0 to be able to support `BIGINT` values properly. If you have some code that you want to run in both MySQL 4.0 and 3.23, you probably can't use the `CAST()` function. You can use the following technique to get a signed result when subtracting two unsigned integer columns `ucol1` and `ucol2`:

```
mysql> SELECT (ucol1+0.0)-(ucol2+0.0) FROM ...;
```

The idea is that the columns are converted to floating-point values before the subtraction occurs.

If you have a problem with `UNSIGNED` columns in old MySQL applications when porting them to MySQL 4.0, you can use the `--sql-mode=NO_UNSIGNED_SUBTRACTION` option when starting `mysqld`. However, as long as you use this option, you are not able to make efficient use of the `BIGINT UNSIGNED` column type.

12.9. Other Functions

12.9.1. Bit Functions

MySQL uses `BIGINT` (64-bit) arithmetic for bit operations, so these operators have a maximum range of 64 bits.

- |

  Bitwise OR:

  ```
  mysql> SELECT 29 | 15;
          -> 31
  ```

  The result is an unsigned 64-bit integer.

- &

  Bitwise AND:

  ```
  mysql> SELECT 29 & 15;
          -> 13
  ```

  The result is an unsigned 64-bit integer.

- ^

  Bitwise XOR:

  ```
  mysql> SELECT 1 ^ 1;
          -> 0
  mysql> SELECT 1 ^ 0;
          -> 1
  mysql> SELECT 11 ^ 3;
          -> 8
  ```

  The result is an unsigned 64-bit integer.

  Bitwise XOR was added in MySQL 4.0.2.

  Shifts a longlong (`BIGINT`) number to the left.

- <<

  ```
  mysql> SELECT 1 << 2;
          -> 4
  ```

  The result is an unsigned 64-bit integer.

-

  >>

  Shifts a longlong (`BIGINT`) number to the right.

  ```
  mysql> SELECT 4 >> 2;
          -> 1
  ```

  The result is an unsigned 64-bit integer.

-

  ~

  Invert all bits.

  ```
  mysql> SELECT 5 & ~1;
          -> 4
  ```

  The result is an unsigned 64-bit integer.

-

  `BIT_COUNT(N)`

  Returns the number of bits that are set in the argument N.

```
mysql> SELECT BIT_COUNT(29);
        -> 4
```

12.9.2. Encryption Functions

The functions in this section encrypt and decrypt data values. If you want to store results from an encryption function that might contain arbitrary byte values, use a BLOB column rather than a CHAR or VARCHAR column to avoid potential problems with trailing space removal that would change data values.

- AES_ENCRYPT(*str*,*key_str*), AES_DECRYPT(*crypt_str*,*key_str*)

  These functions allow encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as "Rijndael." Encoding with a 128-bit key length is used, but you can extend it up to 256 bits by modifying the source. We chose 128 bits because it is much faster and it is usually secure enough.

  The input arguments may be any length. If either argument is NULL, the result of this function is also NULL.

  Because AES is a block-level algorithm, padding is used to encode uneven length strings and so the result string length may be calculated as 16*(trunc(*string_length*/16)+1).

  If AES_DECRYPT() detects invalid data or incorrect padding, it returns NULL. However, it is possible for AES_DECRYPT() to return a non-NULL value (possibly garbage) if the input data or the key is invalid.

  You can use the AES functions to store data in an encrypted form by modifying your queries:

  ```
  INSERT INTO t VALUES (1,AES_ENCRYPT('text','password'));
  ```

  AES_ENCRYPT() and AES_DECRYPT() were added in MySQL 4.0.2, and can be considered the most cryptographically secure encryption functions currently available in MySQL.

-
  DECODE(*crypt_str*,*pass_str*)

  Decrypts the encrypted string *crypt_str* using *pass_str* as the password. *crypt_str* should be a string returned from ENCODE().

-
  ENCODE(*str*,*pass_str*)

  Encrypt *str* using *pass_str* as the password. To decrypt the result, use DECODE().

  The result is a binary string of the same length as *str*. If you want to save it in a column, use a BLOB column type.

-
  DES_DECRYPT(*crypt_str*[,*key_str*])

  Decrypts a string encrypted with DES_ENCRYPT(). On error, this function returns NULL.

  Note that this function works only if MySQL has been configured with SSL support. See Section 5.7.7, "Using Secure Connections".

  If no *key_str* argument is given, DES_DECRYPT() examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have

the SUPER privilege. The key file can be specified with the `--des-key-file` server option.

If you pass this function a `key_str` argument, that string is used as the key for decrypting the message.

If the `crypt_str` argument doesn't look like an encrypted string, MySQL returns the given `crypt_str`.

DES_DECRYPT() was added in MySQL 4.0.1.

*
   DES_ENCRYPT(`str`[,(`key_num`|`key_str`)])

   Encrypts the string with the given key using the Triple-DES algorithm. On error, this function returns NULL.

   Note that this function works only if MySQL has been configured with SSL support. See Section 5.7.7, "Using Secure Connections".

   The encryption key to use is chosen based on the second argument to DES_ENCRYPT(), if one was given:

Argument	Description
No argument	The first key from the DES key file is used.
`key_num`	The given key number (0-9) from the DES key file is used.
`key_str`	The given key string is used to encrypt `str`.

   The key file can be specified with the `--des-key-file` server option.

   The return string is a binary string where the first character is CHAR(128 | key_num).

   The 128 is added to make it easier to recognize an encrypted key. If you use a string key, `key_num` is 127.

   The string length for the result is `new_len = orig_len + (8-(orig_len % 8))+1`.

   Each line in the DES key file has the following format:

   `key_num des_key_str`

   Each `key_num` must be a number in the range from 0 to 9. Lines in the file may be in any order. `des_key_str` is the string that is used to encrypt the message. Between the number and the key there should be at least one space. The first key is the default key that is used if you don't specify any key argument to DES_ENCRYPT()

   You can tell MySQL to read new key values from the key file with the FLUSH DES_KEY_FILE statement. This requires the RELOAD privilege.

   One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

   ```
   mysql> SELECT customer_address FROM customer_table WHERE
           crypted_credit_card = DES_ENCRYPT('credit_card_number');
   ```

   DES_ENCRYPT() was added in MySQL 4.0.1.

*
   ENCRYPT(`str`[,`salt`])

Encrypt *str* using the Unix `crypt()` system call. The *salt* argument should be a string with two characters. (As of MySQL 3.22.16, *salt* may be longer than two characters.) If no *salt* argument is given, a random value is used.

```
mysql> SELECT ENCRYPT('hello');
        -> 'VxuFAJXVARROc'
```

`ENCRYPT()` ignores all but the first eight characters of *str*, at least on some systems. This behavior is determined by the implementation of the underlying `crypt()` system call.

If `crypt()` is not available on your system, `ENCRYPT()` always returns `NULL`. Because of this, we recommend that you use `MD5()` or `SHA1()` instead, because those two functions exist on all platforms.

•

`MD5(str)`

Calculates an MD5 128-bit checksum for the string. The value is returned as a binary string of 32 hex digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key.

```
mysql> SELECT MD5('testing');
        -> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the "RSA Data Security, Inc. MD5 Message-Digest Algorithm."

If you want to convert the value to uppercase, see the description of binary string conversion given in the entry for the `BINARY` operator in Section 12.8, "Cast Functions and Operators".

`MD5()` was added in MySQL 3.23.2.

•

`OLD_PASSWORD(str)`

`OLD_PASSWORD()` is available as of MySQL 4.1, when the implementation of `PASSWORD()` was changed to improve security. `OLD_PASSWORD()` returns the value of the pre-4.1 implementation of `PASSWORD()`. Section 5.6.9, "Password Hashing in MySQL 4.1".

•

`PASSWORD(str)`

Calculates and returns a password string from the plaintext password *str*, or `NULL` if the argument was `NULL`. This is the function that is used for encrypting MySQL passwords for storage in the `Password` column of the `user` grant table.

```
mysql> SELECT PASSWORD('badpwd');
        -> '7f84554057dd964b'
```

`PASSWORD()` encryption is one-way (not reversible).

`PASSWORD()` does not perform password encryption in the same way that Unix passwords are encrypted. See `ENCRYPT()`.

Note: The `PASSWORD()` function is used by the authentication system in MySQL Server, you should *not* use it in your own applications. For that purpose, use `MD5()` or `SHA1()` instead. Also see RFC 2195 for more information about handling passwords and authentication securely in your application.

•

`SHA1(str),SHA(str)`

Calculates an SHA1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hex digits, or `NULL` if the argument was `NULL`. One of the possible uses for this function is as a hash key. You can also use it as a cryptographically safe function for storing passwords.

```
mysql> SELECT SHA1('abc');
        -> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

`SHA1()` was added in MySQL 4.0.2, and can be considered a cryptographically more secure equivalent of `MD5()`. `SHA()` is synonym for `SHA1()`.

12.9.3. Information Functions

- `BENCHMARK(count,expr)`

  The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how fast MySQL processes the expression. The result value is always `0`. The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000,ENCODE('hello','goodbye'));
+----------------------------------------------+
| BENCHMARK(1000000,ENCODE('hello','goodbye')) |
+----------------------------------------------+
|                                            0 |
+----------------------------------------------+
1 row in set (4.74 sec)
```

  The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

- `CHARSET(str)`

  Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
        -> 'latin1'
mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
        -> 'utf8'
mysql> SELECT CHARSET(USER());
        -> 'utf8'
```

  `CHARSET()` was added in MySQL 4.1.0.

- `COERCIBILITY(str)`

  Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
        -> 0
mysql> SELECT COERCIBILITY(USER());
        -> 3
mysql> SELECT COERCIBILITY('abc');
        -> 4
```

  The return values have the following meanings:

Coercib- ility	Meaning	Example
0	Explicit collation	Value with `COLLATE` clause
1	No colla-tion	Concatenation of strings with different collations
2	Implicit collation	Column value
3	System constant	`USER()` return value
4	Coercible	Literal string
5	Ignorable	`NULL` or an expression derived from `NULL`

Before MySQL 4.1.11 and 5.0.3, the return values are shown as follows, and functions such as `USER()` have a coercibility of 2:

Coercib- ility	Meaning	Example
0	Explicit collation	Value with `COLLATE` clause
1	No colla-tion	Concatenation of strings with different collations
2	Implicit collation	Column value
3	Coercible	Literal string

Lower values have higher precedence.

`COERCIBILITY()` was added in MySQL 4.1.1.

-

  `COLLATION(str)`

  Returns the collation for the character set of the string argument.

  ```
  mysql> SELECT COLLATION('abc');
          -> 'latin1_swedish_ci'
  mysql> SELECT COLLATION(_utf8'abc');
          -> 'utf8_general_ci'
  ```

  `COLLATION()` was added in MySQL 4.1.0.

-

  `CONNECTION_ID()`

  Returns the connection ID (thread ID) for the connection. Every connection has its own unique ID.

  ```
  mysql> SELECT CONNECTION_ID();
          -> 23786
  ```

  `CONNECTION_ID()` was added in MySQL 3.23.14.

-

  `CURRENT_USER()`

Returns the username and hostname combination that the current session was authenticated as. This value corresponds to the MySQL account that determines your access privileges. It can be different from the value of USER().

```
mysql> SELECT USER();
        -> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
        -> '@localhost'
```

The example illustrates that although the client specified a username of davida (as indicated by the value of the USER() function), the server authenticated the client using an anonymous user account (as seen by the empty username part of the CURRENT_USER() value). One way this might occur is that there is no account listed in the grant tables for davida.

CURRENT_USER() was added in MySQL 4.0.6. As of MySQL 4.1, the string has the utf8 character set.

- DATABASE()

Returns the default (current) database name. As of MySQL 4.1, the string has the utf8 character set.

```
mysql> SELECT DATABASE();
        -> 'test'
```

If there is no default database, DATABASE() returns NULL as of MySQL 4.1.1, and the empty string before that.

- FOUND_ROWS()

A SELECT statement may include a LIMIT clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the LIMIT, but without running the statement again. To get this row count, include a SQL_CALC_FOUND_ROWS option in the SELECT statement, then invoke FOUND_ROWS() afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
     -> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second SELECT returns a number indicating how many rows the first SELECT would have returned had it been written without the LIMIT clause. (If the preceding SELECT statement does not include the SQL_CALC_FOUND_ROWS option, then FOUND_ROWS() may return a different result when LIMIT is used than when it is not.)

The row count available through FOUND_ROWS() is transient and not intended to be available past the statement following the SELECT SQL_CALC_FOUND_ROWS statment. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using SELECT SQL_CALC_FOUND_ROWS, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without LIMIT, because the result set need not be sent to the client.

SQL_CALC_FOUND_ROWS and FOUND_ROWS() can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using FOUND_ROWS() allows you to determine how many other pages are needed for the rest of the result.

The use of SQL_CALC_FOUND_ROWS and FOUND_ROWS() is more complex for UNION queries than for simple SELECT statements, because LIMIT may occur at multiple places in a UNION. It may be applied to individual SELECT statements in the UNION, or global to the UNION result as a whole.

The intent of SQL_CALC_FOUND_ROWS for UNION is that it should return the row count that would be returned without a global LIMIT. The conditions for use of SQL_CALC_FOUND_ROWS with UNION are:

- The SQL_CALC_FOUND_ROWS keyword must appear in the first SELECT of the UNION.

- The value of FOUND_ROWS() is exact only if UNION ALL is used. If UNION without ALL is used, duplicate removal occurs and the value of FOUND_ROWS() is only approximate.

- If no LIMIT is present in the UNION, SQL_CALC_FOUND_ROWS is ignored and returns the number of rows in the temporary table that is created to process the UNION.

SQL_CALC_FOUND_ROWS and FOUND_ROWS() are available starting at MySQL 4.0.0.

-

LAST_INSERT_ID(), LAST_INSERT_ID(*expr*)

Returns the last automatically generated value that was inserted into an AUTO_INCREMENT column.

```
mysql> SELECT LAST_INSERT_ID();
        -> 195
```

The last ID that was generated is maintained in the server on a per-connection basis. This means the value the function returns to a given client is the most recent AUTO_INCREMENT value generated by that client. The value cannot be affected by other clients, even if they generate AUTO_INCREMENT values of their own. This behavior ensures that you can retrieve your own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of LAST_INSERT_ID() is not changed if you update the AUTO_INCREMENT column of a row with a non-magic value (that is, a value that is not NULL and not 0).

If you insert many rows at the same time with an insert statement, LAST_INSERT_ID() returns the value for the first inserted row. The reason for this is to make it possible to easily reproduce the same INSERT statement against some other server.

If you use INSERT IGNORE and the record is ignored, the AUTO_INCREMENT counter is not incremented and LAST_INSERT_ID() returns 0, which reflects that no record was inserted. (Before MySQL 4.1, AUTO_INCREMENT counter still is incremented and LAST_INSERT_ID() returns the new value.)

If *expr* is given as an argument to LAST_INSERT_ID(), the value of the argument is returned by the function and is remembered as the next value to be returned by LAST_INSERT_ID(). This can be used to simulate sequences:

- Create a table to hold the sequence counter and initialize it:

```
mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);
```

- Use the table to generate sequence numbers like this:

```
mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();
```

  The UPDATE statement increments the sequence counter and causes the next call to LAST_INSERT_ID() to return the updated value. The SELECT statement retrieves that value. The mysql_insert_id() C API function can also be used to get the value. See Section 23.2.3.34, "mysql_insert_id()".

You can generate sequences without calling LAST_INSERT_ID(), but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the UPDATE statement and get their own sequence value with the SELECT statement (or mysql_insert_id()), without affecting or being affected by other clients that generate their own sequence values.

Note that mysql_insert_id() is only updated after INSERT and UPDATE statements, so you cannot use the C API function to retrieve the value for LAST_INSERT_ID(*expr*) after executing other SQL statements like SELECT or SET.

-
  ```
  ROW_COUNT()
  ```

  ROW_COUNT() returns the number of rows updated, inserted, or deleted by the preceding statement. This is the same as the row count that the mysql client displays and the value from the mysql_affected_rows() C API function.

  ```
  mysql> INSERT INTO t VALUES(1),(2),(3);
  Query OK, 3 rows affected (0.00 sec)
  Records: 3  Duplicates: 0  Warnings: 0

  mysql> SELECT ROW_COUNT();
  +-------------+
  | ROW_COUNT() |
  +-------------+
  |           3 |
  +-------------+
  1 row in set (0.00 sec)

  mysql> DELETE FROM t WHERE i IN(1,2);
  Query OK, 2 rows affected (0.00 sec)

  mysql> SELECT ROW_COUNT();
  +-------------+
  | ROW_COUNT() |
  +-------------+
  |           2 |
  +-------------+
  1 row in set (0.00 sec)
  ```

  ROW_COUNT() was added in MySQL 5.0.1.

-
  ```
  SCHEMA()
  ```

  This function is a synonym for DATABASE(). It was added in MySQL 5.0.2.

-
  ```
  SESSION_USER()
  ```

  SESSION_USER() is a synonym for USER().

- SYSTEM_USER()

  SYSTEM_USER() is a synonym for USER().

- USER()

  Returns the current MySQL username and hostname.

  ```
  mysql> SELECT USER();
          -> 'davida@localhost'
  ```

  The value indicates the username you specified when connecting to the server, and the client host from which you connected. The value can be different than that of CURRENT_USER().

  Prior to MySQL 3.22.11, the function value does not include the client hostname. You can extract just the username part, regardless of whether the value includes a hostname part, like this:

  ```
  mysql> SELECT SUBSTRING_INDEX(USER(),'@',1);
          -> 'davida'
  ```

  As of MySQL 4.1, USER() returns a value in the utf8 character set, so you should also make sure that the '@' string literal is interpreted in that character set:

  ```
  mysql> SELECT SUBSTRING_INDEX(USER(),_utf8'@',1);
          -> 'davida'
  ```

- VERSION()

  Returns a string that indicates the MySQL server version. As of MySQL 4.1, the string has the utf8 character set.

  ```
  mysql> SELECT VERSION();
          -> '4.1.3-beta-log'
  ```

  Note that if your version string ends with -log this means that logging is enabled.

12.9.4. Miscellaneous Functions

- DEFAULT(*col_name*)

  Returns the default value for a table column. Starting from MySQL 5.0.2, you get an error if the column doesn't have a default value.

  ```
  mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
  ```

  DEFAULT() was added in MySQL 4.1.0.

- FORMAT(*X*,*D*)

  Formats the number X to a format like '#,###,###.##', rounded to D decimals, and returns the result as a string. If D is 0, the result has no decimal point or fractional part.

  ```
  mysql> SELECT FORMAT(12332.123456, 4);
          -> '12,332.1235'
  ```

```
mysql> SELECT FORMAT(12332.1,4);
        -> '12,332.1000'
mysql> SELECT FORMAT(12332.2,0);
        -> '12,332'
```

-

  GET_LOCK(*str*,*timeout*)

  Tries to obtain a lock with a name given by the string *str*, with a timeout of *timeout* seconds. Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with mysqladmin kill). If you have a lock obtained with GET_LOCK(), it is released when you execute RELEASE_LOCK(), execute a new GET_LOCK(), or your connection terminates (either normally or abnormally).

  This function can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked by one client, GET_LOCK() blocks any request by another client for a lock with the same name. This allows clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also allows a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form *db_name.str* or *app_name.str*.

```
mysql> SELECT GET_LOCK('lock1',10);
        -> 1
mysql> SELECT IS_FREE_LOCK('lock2');
        -> 1
mysql> SELECT GET_LOCK('lock2',10);
        -> 1
mysql> SELECT RELEASE_LOCK('lock2');
        -> 1
mysql> SELECT RELEASE_LOCK('lock1');
        -> NULL
```

  Note that the second RELEASE_LOCK() call returns NULL because the lock 'lock1' was automatically released by the second GET_LOCK() call.

-

  INET_ATON(*expr*)

  Given the dotted-quad representation of a network address as a string, returns an integer that represents the numeric value of the address. Addresses may be 4- or 8-byte addresses.

```
mysql> SELECT INET_ATON('209.207.224.40');
        -> 3520061480
```

  The generated number is always in network byte order. For the example just shown, the number is calculated as 209*256^3 + 207*256^2 + 224*256 + 40.

  As of MySQL 4.1.2, INET_ATON() also understands short-form IP addresses:

```
mysql> SELECT INET_ATON('127.0.0.1'), INET_ATON('127.1');
        -> 2130706433, 2130706433
```

  NOTE: When storing values generated by INET_ATON(), it is recommended that you use an INT UNSIGNED column. If you use a (signed) INT column, then values corresponding to IP addresses for which the first octet is greater than 127 will be truncated to 2147483647 (that is, the value returned by INET_ATON('127.255.255.255')). See Section 11.2, "Numeric Types".

INET_ATON() was added in MySQL 3.23.15.

- INET_NTOA(*expr*)

  Given a numeric network address (4 or 8 byte), returns the dotted-quad representation of the address as a string.

  ```
  mysql> SELECT INET_NTOA(3520061480);
          -> '209.207.224.40'
  ```

  INET_NTOA() was added in MySQL 3.23.15.

- IS_FREE_LOCK(*str*)

  Checks whether the lock named *str* is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and NULL on errors (such as incorrect arguments).

  IS_FREE_LOCK() was added in MySQL 4.0.2.

- IS_USED_LOCK(*str*)

  Checks whether the lock named *str* is in use (that is, locked). If so, it returns the connection identifier of the client that holds the lock. Otherwise, it returns NULL.

  IS_USED_LOCK() was added in MySQL 4.1.0.

- MASTER_POS_WAIT(*log_name*,*log_pos*[,*timeout*])

  This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events it had to wait for to get to the specified position. The function returns NULL if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns -1 if the timeout has been exceeded. If the slave SQL thread stops while MASTER_POS_WAIT() is waiting, the function returns NULL. If the slave is past the specified position, the function returns immediately.

  If a *timeout* value is specified, MASTER_POS_WAIT() stops waiting when *timeout* seconds have elapsed. *timeout* must be greater than 0; a zero or negative *timeout* means no timeout.

  MASTER_POS_WAIT() was added in MySQL 3.23.32. The *timeout* argument was added in 4.0.10.

- RELEASE_LOCK(*str*)

  Releases the lock named by the string *str* that was obtained with GET_LOCK(). Returns 1 if the lock was released, 0 if the lock wasn't locked by this thread (in which case the lock is not released), and NULL if the named lock didn't exist. The lock does not exist if it was never obtained by a call to GET_LOCK() or if it has previously been released.

  The DO statement is convenient to use with RELEASE_LOCK(). See Section 13.2.2, "DO Syntax".

- UUID()

  Returns a Universal Unique Identifier (UUID) generated according to "DCE 1.1: Remote Pro-

cedure Call" (Appendix A) CAE (Common Applications Environment) Specifications published by The Open Group in October 1997 (Document Number C706).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

A UUID is a 128-bit number represented by a string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from a timestamp.

- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).

- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host computer has no Ethernet card, or we do not know how to find the hardware address of an interface on your operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have *very* low probability.

  Currently, the MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
        -> '6ccd780c-baba-1026-9564-0040f4311e29'
```

Note that `UUID()` does not yet work with replication.

`UUID()` was added in MySQL 4.1.2.

12.10. Functions and Modifiers for Use with `GROUP BY` Clauses

12.10.1. `GROUP BY` (Aggregate) Functions

This section describes group (aggregate) functions that operate on sets of values. Unless otherwise stated, group functions ignore `NULL` values.

If you use an group function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows.

- `AVG([DISTINCT] expr)`

  Returns the average value of `expr`. The `DISTINCT` option can be used as of MySQL 5.0.3 to return the averge of the distinct values of `expr`.

  `AVG()` returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, AVG(test_score)
    ->          FROM student
    ->          GROUP BY student_name;
```

-

  `BIT_AND(expr)`

  Returns the bitwise `AND` of all bits in `expr`. The calculation is performed with 64-bit (`BIGINT`)

precision.

As of MySQL 4.0.17, this function returns `18446744073709551615` if there were no matching rows. (This is an unsigned `BIGINT` value with all bits set to 1.) Before 4.0.17, the function returns `-1` if there were no matching rows.

- `BIT_OR(expr)`

  Returns the bitwise `OR` of all bits in `expr`. The calculation is performed with 64-bit (`BIGINT`) precision.

  This function returns `0` if there were no matching rows.

- `BIT_XOR(expr)`

  Returns the bitwise `XOR` of all bits in `expr`. The calculation is performed with 64-bit (`BIGINT`) precision.

  This function returns `0` if there were no matching rows.

  This function is available as of MySQL 4.1.1.

- `COUNT(expr)`

  Returns a count of the number of non-`NULL` values in the rows retrieved by a `SELECT` statement.

  `COUNT()` returns `0` if there were no matching rows.

  ```
  mysql> SELECT student.student_name,COUNT(*)
      ->        FROM student,course
      ->        WHERE student.student_id=course.student_id
      ->        GROUP BY student_name;
  ```

  `COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain `NULL` values.

  `COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

  ```
  mysql> SELECT COUNT(*) FROM student;
  ```

  This optimization applies only to `MyISAM` and `ISAM` tables only, because an exact record count is stored for these table types and can be accessed very quickly. For transactional storage engines (`InnoDB`, `BDB`), storing an exact row count is more problematic because multiple transactions may be occurring, each of which may affect the count.

- `COUNT(DISTINCT expr,[expr...])`

  Returns a count of the number of different non-`NULL` values.

  `COUNT(DISTINCT)` returns `0` if there were no matching rows.

  ```
  mysql> SELECT COUNT(DISTINCT results) FROM student;
  ```

  In MySQL, you can get the number of distinct expression combinations that don't contain `NULL` by giving a list of expressions. In standard SQL, you would have to do a concatenation of all ex-

pressions inside `COUNT(DISTINCT ...)`.

`COUNT(DISTINCT ...)` was added in MySQL 3.23.2.

- `GROUP_CONCAT(expr)`

  This function returns a string result with the concatenated non-`NULL` values from a group. It returns `NULL` if there are no non-`NULL` values. The full syntax is as follows:

  ```
  GROUP_CONCAT([DISTINCT] expr [,expr ...]
               [ORDER BY {unsigned_integer | col_name | expr}
                   [ASC | DESC] [,col_name ...]]
               [SEPARATOR str_val])
  ```

  ```
  mysql> SELECT student_name,
      ->        GROUP_CONCAT(test_score)
      ->        FROM student
      ->        GROUP BY student_name;
  ```

  Or:

  ```
  mysql> SELECT student_name,
      ->        GROUP_CONCAT(DISTINCT test_score
      ->                ORDER BY test_score DESC SEPARATOR ' ')
      ->        FROM student
      ->        GROUP BY student_name;
  ```

  In MySQL, you can get the concatenated values of expression combinations. You can eliminate duplicate values by using `DISTINCT`. If you want to sort values in the result, you should use `ORDER BY` clause. To sort in reverse order, add the `DESC` (descending) keyword to the name of the column you are sorting by in the `ORDER BY` clause. The default is ascending order; this may be specified explicitly using the `ASC` keyword. `SEPARATOR` is followed by the string value that should be inserted between values of result. The default is a comma (','). You can remove the separator altogether by specifying `SEPARATOR ''`.

  You can set a maximum allowed length with the `group_concat_max_len` system variable. The syntax to do this at runtime is as follows, where `val` is an unsigned integer:

  ```
  SET [SESSION | GLOBAL] group_concat_max_len = val;
  ```

  If a maximum length has been set, the result is truncated to this maximum length.

  `GROUP_CONCAT()` was added in MySQL 4.1.

  Note: Before MySQL 4.1.6, there are some small limitations with `GROUP_CONCAT()` for `BLOB` and `TEXT` values when it comes to using `DISTINCT` together with `ORDER BY`. To work around this limitation, use `MID(expr,1,255)` instead.

- `MIN([DISTINCT] expr)`, `MAX([DISTINCT] expr)`

  Returns the minimum or maximum value of `expr`. `MIN()` and `MAX()` may take a string argument; in such cases they return the minimum or maximum string value. See Section 7.4.5, "How MySQL Uses Indexes". The `DISTINCT` keyword can be used as of MySQL 5.0.0 to find the minimum or maximum of the distinct values of `expr`; this is supported, but produces the same result as omitting `DISTINCT`.

  `MIN()` and `MAX()` return `NULL` if there were no matching rows.

  ```
  mysql> SELECT student_name, MIN(test_score), MAX(test_score)
      ->           FROM student
  ```

```
            ->              GROUP BY student_name;
```

For `MIN()`, `MAX()`, and other aggregate functions, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This will be rectified.

- `STD(expr)`, `STDDEV(expr)`

  Returns the population standard deviation of `expr`. This is an extension to standard SQL. The `STDDEV()` form of this function is provided for Oracle compatibility. As of MySQL 5.0.3, the standard SQL function `STDDEV_POP()` can be used instead.

  These functions return `NULL` if there were no matching rows.

- `STDDEV_POP(expr)`

  Returns the population standard deviation of `expr` (the square root of `VAR_POP()`). This function was added in MySQL 5.0.3. Before 5.0.3, you can use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

  `STDDEV_POP()` returns `NULL` if there were no matching rows.

- `STDDEV_SAMP(expr)`

  Returns the sample standard deviation of `expr` (the square root of `VAR_SAMP()`. This function was added in MySQL 5.0.3.

  `STDDEV_SAMP()` returns `NULL` if there were no matching rows.

- `SUM([DISTINCT] expr)`

  Returns the sum of `expr`. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used as of MySQL 5.0.0 to sum only the distinct values of `expr`.

  `SUM()` returns `NULL` if there were no matching rows.

- `VAR_POP(expr)`

  Returns the population standard variance of `expr`. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. This function was added in MySQL 5.0.3. Before 5.0.3, you can use `VARIANCE()`, which is equivalent but not standard SQL.

  `VAR_POP()` returns `NULL` if there were no matching rows.

- `VAR_SAMP(expr)`

  Returns the sample variance of `expr`. That is, the denominator is the number of rows minus one. This function was added in MySQL 5.0.3.

  `VAR_SAMP()` returns `NULL` if there were no matching rows.

- `VARIANCE(expr)`

  Returns the population standard variance of `expr`. This is an extension to standard SQL, available in MySQL 4.1 or later. As of MySQL 5.0.3, the standard SQL function `VAR_POP()` can be used instead.

VARIANCE() returns NULL if there were no matching rows.

12.10.2. GROUP BY Modifiers

As of MySQL 4.1.1, the GROUP BY clause allows a WITH ROLLUP modifier that causes extra rows to be added to the summary output. These rows represent higher-level (or super-aggregate) summary operations. ROLLUP thus allows you to answer questions at multiple levels of analysis with a single query. It can be used, for example, to provide support for OLAP (Online Analytical Processing) operations.

As an illustration, suppose that a table named sales has year, country, product, and profit columns for recording sales profitability:

```
CREATE TABLE sales
(
    year    INT NOT NULL,
    country VARCHAR(20) NOT NULL,
    product VARCHAR(32) NOT NULL,
    profit  INT
);
```

The table's contents can be summarized per year with a simple GROUP BY like this:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year;
+------+-------------+
| year | SUM(profit) |
+------+-------------+
| 2000 |        4525 |
| 2001 |        3010 |
+------+-------------+
```

This output shows the total profit for each year, but if you also want to determine the total profit summed over all years, you must add up the individual values yourself or run an additional query.

Or you can use ROLLUP, which provides both levels of analysis with a single query. Adding a WITH ROLLUP modifier to the GROUP BY clause causes the query to produce another row that shows the grand total over all year values:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year WITH ROLLUP;
+------+-------------+
| year | SUM(profit) |
+------+-------------+
| 2000 |        4525 |
| 2001 |        3010 |
| NULL |        7535 |
+------+-------------+
```

The grand total super-aggregate line is identified by the value NULL in the year column.

ROLLUP has a more complex effect when there are multiple GROUP BY columns. In this case, each time there is a "break" (change in value) in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without ROLLUP, a summary on the sales table based on year, country, and product might look like this:

```
mysql> SELECT year, country, product, SUM(profit)
    -> FROM sales
    -> GROUP BY year, country, product;
+------+---------+------------+-------------+
| year | country | product    | SUM(profit) |
```

```
+------+---------+------------+-------------+
| 2000 | Finland | Computer   |        1500 |
| 2000 | Finland | Phone      |         100 |
| 2000 | India   | Calculator |         150 |
| 2000 | India   | Computer   |        1200 |
| 2000 | USA     | Calculator |          75 |
| 2000 | USA     | Computer   |        1500 |
| 2001 | Finland | Phone      |          10 |
| 2001 | USA     | Calculator |          50 |
| 2001 | USA     | Computer   |        2700 |
| 2001 | USA     | TV         |         250 |
+------+---------+------------+-------------+
```

The output indicates summary values only at the year/country/product level of analysis. When ROLLUP is added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit)
    -> FROM sales
    -> GROUP BY year, country, product WITH ROLLUP;
+------+---------+------------+-------------+
| year | country | product    | SUM(profit) |
+------+---------+------------+-------------+
| 2000 | Finland | Computer   |        1500 |
| 2000 | Finland | Phone      |         100 |
| 2000 | Finland | NULL       |        1600 |
| 2000 | India   | Calculator |         150 |
| 2000 | India   | Computer   |        1200 |
| 2000 | India   | NULL       |        1350 |
| 2000 | USA     | Calculator |          75 |
| 2000 | USA     | Computer   |        1500 |
| 2000 | USA     | NULL       |        1575 |
| 2000 | NULL    | NULL       |        4525 |
| 2001 | Finland | Phone      |          10 |
| 2001 | Finland | NULL       |          10 |
| 2001 | USA     | Calculator |          50 |
| 2001 | USA     | Computer   |        2700 |
| 2001 | USA     | TV         |         250 |
| 2001 | USA     | NULL       |        3000 |
| 2001 | NULL    | NULL       |        3010 |
| NULL | NULL    | NULL       |        7535 |
+------+---------+------------+-------------+
```

For this query, adding ROLLUP causes the output to include summary information at four levels of analysis, not just one. Here's how to interpret the ROLLUP output:

- Following each set of product rows for a given year and country, an extra summary row is produced showing the total for all products. These rows have the product column set to NULL.

- Following each set of rows for a given year, an extra summary row is produced showing the total for all countries and products. These rows have the country and products columns set to NULL.

- Finally, following all other rows, an extra summary row is produced showing the grand total for all years, countries, and products. This row has the year, country, and products columns set to NULL.

Other Considerations When using ROLLUP

The following items list some behaviors specific to the MySQL implementation of ROLLUP:

When you use ROLLUP, you cannot also use an ORDER BY clause to sort the results. In other words, ROLLUP and ORDER BY are mutually exclusive. However, you still have some control over sort order. GROUP BY in MySQL sorts results, and you can use explicit ASC and DESC keywords with columns named in the GROUP BY list to specify sort order for individual columns. (The high-

er-level summary rows added by ROLLUP still appear after the rows from which they are calculated, regardless of the sort order.)

LIMIT can be used to restrict the number of rows returned to the client. LIMIT is applied after ROLLUP, so the limit applies against the extra rows added by ROLLUP. For example:

```
mysql> SELECT year, country, product, SUM(profit)
    -> FROM sales
    -> GROUP BY year, country, product WITH ROLLUP
    -> LIMIT 5;
+------+---------+------------+-------------+
| year | country | product    | SUM(profit) |
+------+---------+------------+-------------+
| 2000 | Finland | Computer   |        1500 |
| 2000 | Finland | Phone      |         100 |
| 2000 | Finland | NULL       |        1600 |
| 2000 | India   | Calculator |         150 |
| 2000 | India   | Computer   |        1200 |
+------+---------+------------+-------------+
```

Using LIMIT with ROLLUP may produce results that are more difficult to interpret, because you have less context for understanding the super-aggregate rows.

The NULL indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the GROUP BY clause following the leftmost one that has changed value. For any column in the result set with a name that is a lexical match to any of those names, its value is set to NULL. (If you specify grouping columns by column number, the server identifies which columns to set to NULL by number.)

Because the NULL values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you cannot test them as NULL values within the query itself. For example, you cannot add HAVING product IS NULL to the query to eliminate from the output all but the super-aggregate rows.

On the other hand, the NULL values do appear as NULL on the client side and can be tested as such using any MySQL client programming interface.

12.10.3. GROUP BY with Hidden Fields

MySQL extends the use of GROUP BY so that you can use columns or calculations in the SELECT list that don't appear in the GROUP BY clause. This stands for *any possible value for this group*. You can use this to get better performance by avoiding sorting and grouping on unnecessary items. For example, you don't need to group on customer.name in the following query:

```
mysql> SELECT order.custid, customer.name, MAX(payments)
    ->         FROM order,customer
    ->         WHERE order.custid = customer.custid
    ->         GROUP BY order.custid;
```

In standard SQL, you would have to add customer.name to the GROUP BY clause. In MySQL, the name is redundant if you don't run in ANSI mode.

Do *not* use this feature if the columns you omit from the GROUP BY part are not unique in the group! You get unpredictable results.

In some cases, you can use MIN() and MAX() to obtain a specific column value even if it isn't unique. The following gives the value of column from the row containing the smallest value in the sort column:

```
SUBSTR(MIN(CONCAT(RPAD(sort,6,' '),column)),7)
```

See Section 3.6.4, "The Rows Holding the Group-wise Maximum of a Certain Field".

Note that if you are using MySQL 3.22 (or earlier) or if you are trying to follow standard SQL, you can't use expressions in GROUP BY or ORDER BY clauses. You can work around this limitation by using an alias for the expression:

```
mysql> SELECT id,FLOOR(value/100) AS val FROM tbl_name
    ->     GROUP BY id, val ORDER BY val;
```

In MySQL 3.23 and up, aliases are unnecessary. You can use expressions in GROUP BY and OR-DER BY clauses. For example:

```
mysql> SELECT id, FLOOR(value/100) FROM tbl_name ORDER BY RAND();
```

Chapter 13. SQL Statement Syntax

This chapter describes the syntax for the SQL statements supported in MySQL.

13.1. Data Definition Statements

13.1.1. `ALTER DATABASE` Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
alter_specification [, alter_specification] ...

alter_specification:
[DEFAULT] CHARACTER SET charset_name
| [DEFAULT] COLLATE collation_name
```

`ALTER DATABASE` allows you to change the overall characteristics of a database. These character-istics are stored in the `db.opt` file in the database directory. To use `ALTER DATABASE`, you need the `ALTER` privilege on the database.

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. Character set and collation names are discussed in Chapter 10, *Character Set Support*.

`ALTER DATABASE` was added in MySQL 4.1.1. Beginning with MySQL 4.1.8, the database name can be omitted. The statement applies to the default database in this case. `ALTER SCHEMA` can be used as of MySQL 5.0.2.

13.1.2. `ALTER TABLE` Syntax

```
ALTER [IGNORE] TABLE tbl_name
alter_specification [, alter_specification] ...

alter_specification:
ADD [COLUMN] column_definition [FIRST | AFTER col_name ]
 | ADD [COLUMN] (column_definition,...)
 | ADD INDEX [index_name] [index_type] (index_col_name,...)
 | ADD [CONSTRAINT [symbol]]
PRIMARY KEY [index_type] (index_col_name,...)
 | ADD [CONSTRAINT [symbol]]
UNIQUE [index_name] [index_type] (index_col_name,...)
 | ADD [FULLTEXT|SPATIAL] [index_name] (index_col_name,...)
 | ADD [CONSTRAINT [symbol]]
FOREIGN KEY [index_name] (index_col_name,...)
[reference_definition]
 | ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
 | CHANGE [COLUMN] old_col_name column_definition
[FIRST|AFTER col_name]
 | MODIFY [COLUMN] column_definition [FIRST | AFTER col_name]
 | DROP [COLUMN] col_name
 | DROP PRIMARY KEY
 | DROP INDEX index_name
 | DROP FOREIGN KEY fk_symbol
 | DISABLE KEYS
 | ENABLE KEYS
 | RENAME [TO] new_tbl_name
 | ORDER BY col_name
 | CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
 | [DEFAULT] CHARACTER SET charset_name [COLLATE collation_name]
 | DISCARD TABLESPACE
 | IMPORT TABLESPACE
 | table_options
```

`ALTER TABLE` allows you to change the structure of an existing table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change the comment for the table and type of the table.

The syntax for many of the allowable alterations is similar to clauses of the `CREATE TABLE` statement. This includes `table_options` modifications, for options such as `ENGINE`, `AUTO_INCREMENT`, and `AVG_ROW_LENGTH`. See Section 13.1.5, "`CREATE TABLE` Syntax".

Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. In MySQL 4.1 and up, these warnings can be displayed with `SHOW WARNINGS`. See Section 13.5.4.22, "`SHOW WARNINGS` Syntax".

If you use `ALTER TABLE` to change a column specification but `DESCRIBE` `tbl_name` indicates that your column was not changed, it is possible that MySQL ignored your modification for one of the reasons described in Section 13.1.5.1, "Silent Column Specification Changes". For example, if you try to change a `VARCHAR` column to `CHAR`, MySQL still uses `VARCHAR` if the table contains other variable-length columns.

`ALTER TABLE` works by making a temporary copy of the original table. The alteration is performed on the copy, then the original table is deleted and the new one is renamed. While `ALTER TABLE` is executing, the original table is readable by other clients. Updates and writes to the table are stalled until the new table is ready, then are automatically redirected to the new table without any failed updates.

Note that if you use any other option to `ALTER TABLE` than `RENAME`, MySQL always creates a temporary table, even if the data wouldn't strictly need to be copied (such as when you change the name of a column). We plan to fix this in the future, but because `ALTER TABLE` is not a statement that is normally used frequently, this isn't high on our TODO list. For `MyISAM` tables, you can speed up the index re-creation operation (which is the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

- To use `ALTER TABLE`, you need `ALTER`, `INSERT`, and `CREATE` privileges for the table.

- `IGNORE` is a MySQL extension to standard SQL. It controls how `ALTER TABLE` works if there are duplicates on unique keys in the new table or if warnings occur when `STRICT` mode is enabled. If `IGNORE` isn't specified, the copy is aborted and rolled back if duplicate-key errors occur. If `IGNORE` is specified, then for rows with duplicates on a unique key, only the first row is used. The others conflicting rows are deleted. Wrong values are truncated to the closest matching acceptable value.

- You can issue multiple `ADD`, `ALTER`, `DROP`, and `CHANGE` clauses in a single `ALTER TABLE` statement, separated by commas. This is a MySQL extension to standard SQL, which allows only one of each clause per `ALTER TABLE` statement. For example, to drop multiple columns in a single statement:

  ```
  mysql> ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
  ```

- `CHANGE` `col_name`, `DROP` `col_name`, and `DROP INDEX` are MySQL extensions to standard SQL.

- `MODIFY` is an Oracle extension to `ALTER TABLE`.

- The word `COLUMN` is purely optional and can be omitted.

- If you use `ALTER TABLE` `tbl_name` `RENAME TO` `new_tbl_name` without any other options, MySQL simply renames any files that correspond to the table `tbl_name`. There is no need to create a temporary table. (You can also use the `RENAME TABLE` statement to rename tables. See Section 13.1.9, "`RENAME TABLE` Syntax".)

- `column_definition` clauses use the same syntax for `ADD` and `CHANGE` as for `CREATE TABLE`. Note that this syntax includes the column name, not just the column type. See Section 13.1.5, "`CREATE TABLE` Syntax".

- You can rename a column using a CHANGE `old_col_name` `column_definition` clause. To do so, specify the old and new column names and the type that the column currently has. For example, to rename an INTEGER column from a to b, you can do this:

    ```
    mysql> ALTER TABLE t1 CHANGE a b INTEGER;
    ```

    If you want to change a column's type but not the name, CHANGE syntax still requires an old and new column name, even if they are the same. For example:

    ```
    mysql> ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
    ```

    However, as of MySQL 3.22.16a, you can also use MODIFY to change a column's type without renaming it:

    ```
    mysql> ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
    ```

- If you use CHANGE or MODIFY to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

- When you change a column type using CHANGE or MODIFY, MySQL tries to convert existing column values to the new type as well as possible.

- In MySQL 3.22 or later, you can use FIRST or AFTER `col_name` to add a column at a specific position within a table row. The default is to add the column last. From MySQL 4.0.1 on, you can also use FIRST and AFTER in CHANGE or MODIFY operations.

- ALTER COLUMN specifies a new default value for a column or removes the old default value. If the old default is removed and the column can be NULL, the new default is NULL. If the column cannot be NULL, MySQL assigns a default value, as described in Section 13.1.5, "CREATE TABLE Syntax".

- DROP INDEX removes an index. This is a MySQL extension to standard SQL. See Section 13.1.7, "DROP INDEX Syntax".

- If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well.

- If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use DROP TABLE instead.

- DROP PRIMARY KEY drops the primary index. (Prior to MySQL 4.1.2, if no primary index exists, DROP PRIMARY KEY drops the first UNIQUE index in the table. MySQL marks the first UNIQUE key as the PRIMARY KEY if no PRIMARY KEY was specified explicitly.)

    If you add a UNIQUE INDEX or PRIMARY KEY to a table, it is stored before any non-unique index so that MySQL can detect duplicate keys as early as possible.

- ORDER BY allows you to create the new table with the rows in a specific order. Note that the table does not remain in this order after inserts and deletes. This option is mainly useful when you know that you are mostly going to query the rows in a certain order; by using this option after big changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

- If you use ALTER TABLE on a MyISAM table, all non-unique indexes are created in a separate

batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

As of MySQL 4.0, this feature can be activated explicitly. `ALTER TABLE ... DISABLE KEYS` tells MySQL to stop updating non-unique indexes for a `MyISAM` table. `ALTER TABLE ... ENABLE KEYS` then should be used to re-create missing indexes. MySQL does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

•

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` storage engine, which implements `ADD [CONSTRAINT [symbol]] FOREIGN KEY (...) REFER-ENCES ... (...)`. See Section 15.7.4, "`FOREIGN KEY` Constraints". For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by all storage engines. See Section 13.1.5, "`CREATE TABLE` Syntax". The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See Section 1.8.5, "MySQL Differences from Standard SQL".

•

Starting from MySQL 4.0.13, `InnoDB` supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE yourtablename DROP FOREIGN KEY fk_symbol;
```

For more information, see Section 15.7.4, "`FOREIGN KEY` Constraints".

• `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.

•

From MySQL 4.1.2 on, if you want to change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

This is useful, for example, after upgrading from MySQL 4.0.x to 4.1.x. See Section 10.10, "Upgrading Character Sets from MySQL 4.0".

Warning: The preceding operation converts column values between the character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer will have a character set and a subsequent `CON-VERT TO` operation will not apply to them.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you don't specify the character set for a new column you add to a table (for example, with `ALTER`

```
TABLE ... ADD column).
```

Warning: From MySQL 4.1.2 and up, ALTER TABLE ... DEFAULT CHARACTER SET and ALTER TABLE ... CHARACTER SET are equivalent and change only the default table character set. In MySQL 4.1 releases before 4.1.2, ALTER TABLE ... DEFAULT CHAR-ACTER SET changes the default character set, but ALTER TABLE ... CHARACTER SET (without DEFAULT) changes the default character set *and also* converts all columns to the new character set.

- For an InnoDB table that is created with its own tablespace in an .ibd file, that file can be discarded and imported. To discard the .ibd file, use this statement:

  ```
  ALTER TABLE tbl_name DISCARD TABLESPACE;
  ```

  This deletes the current .ibd file, so be sure that you have a backup first. Attempting to access the table while the tablespace file is discarded results in an error.

  To import the backup .ibd file back into the table, copy it into the database directory, then issue this statement:

  ```
  ALTER TABLE tbl_name IMPORT TABLESPACE;
  ```

  See Section 15.7.6, "Using Per-Table Tablespaces".

- With the mysql_info() C API function, you can find out how many records were copied, and (when IGNORE is used) how many records were deleted due to duplication of unique key values. See Section 23.2.3.32, "mysql_info()".

Here are some examples that show uses of ALTER TABLE. Begin with a table t1 that is created as shown here:

```
mysql> CREATE TABLE t1 (a INTEGER,b CHAR(10));
```

To rename the table from t1 to t2:

```
mysql> ALTER TABLE t1 RENAME t2;
```

To change column a from INTEGER to TINYINT NOT NULL (leaving the name the same), and to change column b from CHAR(10) to CHAR(20) as well as renaming it from b to c:

```
mysql> ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new TIMESTAMP column named d:

```
mysql> ALTER TABLE t2 ADD d TIMESTAMP;
```

To add indexes on column d and on column a:

```
mysql> ALTER TABLE t2 ADD INDEX (d), ADD INDEX (a);
```

To remove column c:

```
mysql> ALTER TABLE t2 DROP COLUMN c;
```

To add a new AUTO_INCREMENT integer column named c:

```
mysql> ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,
    ->     ADD PRIMARY KEY (c);
```

Note that we indexed `c` (as a `PRIMARY KEY`), because `AUTO_INCREMENT` columns must be indexed, and also that we declare `c` as `NOT NULL`, because primary key columns cannot be `NULL`.

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers for you automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option. See Section 13.5.3, "`SET` Syntax".

From MySQL 4.1.12 and MySQL 5.0.3, you can use the `ALTER TABLE ... AUTO_INCREMENT=value` table option for `InnoDB` tables to set the sequence number for new rows if the value is greater than the maximum value in the `AUTO_INCREMENT` column. *If the value is less than the current maximum value in the column, no error message is given and the current sequence value is not changed.*

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

See Section A.7.1, "Problems with `ALTER TABLE`".

13.1.3. `CREATE DATABASE` Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
[create_specification [, create_specification] ...]

create_specification:
  [DEFAULT] CHARACTER SET charset_name
| [DEFAULT] COLLATE collation_name
```

`CREATE DATABASE` creates a database with the given name. To use `CREATE DATABASE`, you need the `CREATE` privilege on the database.

Rules for allowable database names are given in Section 9.2, "Database, Table, Index, Column, and Alias Names". An error occurs if the database exists and you didn't specify `IF NOT EXISTS`.

As of MySQL 4.1.1, `create_specification` options can be given to specify database characteristics. Database characteristics are stored in the `db.opt` file in the database directory. The `CHARACTER SET` clause specifies the default database character set. The `COLLATE` clause specifies the default database collation. Character set and collation names are discussed in Chapter 10, *Character Set Support*.

Databases in MySQL are implemented as directories containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement only creates a directory under the MySQL data directory (and the `db.opt` file, for MySQL 4.1.1 and up).

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

`CREATE SCHEMA` can be used as of MySQL 5.0.2.

You can also use the `mysqladmin` program to create databases. See Section 8.4, "mysqladmin — Client for Administering a MySQL Server".

13.1.4. `CREATE INDEX` Syntax

```
CREATE [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
[USING index_type]
```

```
        ON tbl_name (index_col_name,...)

        index_col_name:
        col_name [(length)] [ASC | DESC]
```

In MySQL 3.22 or later, `CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See Section 13.1.2, "`ALTER TABLE` Syntax". The `CREATE INDEX` statement doesn't do anything prior to MySQL 3.22.

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See Section 13.1.5, "`CREATE TABLE` Syntax". `CREATE INDEX` allows you to add indexes to existing tables.

A column list of the form `(col1,col2,...)` creates a multiple-column index. Index values are formed by concatenating the values of the given columns.

For `CHAR` and `VARCHAR` columns, indexes can be created that use only part of a column, using `col_name(length)` syntax to index a prefix consisting of the first `length` characters of each column value. `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given.

The statement shown here creates an index using the first 10 characters of the `name` column:

```
        CREATE INDEX part_of_name ON customer (name(10));
```

Because most names usually differ in the first 10 characters, this index should not be much slower than an index created from the entire `name` column. Also, using partial columns for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations!

Prefixes can be up to 255 bytes long (or 1000 bytes for `MyISAM` and `InnoDB` tables as of MySQL 4.1.2). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE INDEX` statements is interpreted as number of characters. Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

You can add an index on a column that can have `NULL` values only if you are using MySQL 3.23.2 or newer and are using the `MyISAM`, `InnoDB`, or `BDB` table type. You can only add an index on a `BLOB` or `TEXT` column if you are using MySQL 3.23.2 or newer and are using the `MyISAM` or `BDB` table type, or MySQL 4.0.14 or newer and the `InnoDB` table type.

An `index_col_name` specification can end with `ASC` or `DESC`. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently they are parsed but ignored; index values are always stored in ascending order.

From MySQL 4.1.0 on, some storage engines allow you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. The allowable `type_name` values supported by different storage engines are shown in the following table. Where multiple index types are listed, the first one is the default when no `index_type` specifier is given.

Storage Engine	Allowable Index Types
`MyISAM`	`BTREE`
`InnoDB`	`BTREE`
`MEMORY/HEAP`	`HASH, BTREE`

Example:

```
        CREATE TABLE lookup (id INT) ENGINE = MEMORY;
        CREATE INDEX id_index USING BTREE ON lookup (id);
```

`TYPE type_name` can be used as a synonym for `USING type_name` to specify an index type. However, `USING` is the preferred form. Also, the index name that precedes the index type in the in-

dex specification syntax is not optional with TYPE. This is because, unlike USING, TYPE is not a reserved word and thus is interpreted as an index name.

If you specify an index type that is not legal for a storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

For more information about how MySQL uses indexes, see Section 7.4.5, "How MySQL Uses Indexes".

FULLTEXT indexes can index only CHAR, VARCHAR, and TEXT columns, and only in MyISAM tables. FULLTEXT indexes are available in MySQL 3.23.23 or later. Section 12.7, "Full-Text Search Functions".

SPATIAL indexes can index only spatial columns, and only in MyISAM tables. SPATIAL indexes are available in MySQL 4.1 or later. Spatial column types are described in Chapter 17, *Spatial Extensions in MySQL.*

13.1.5. `CREATE  TABLE` Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
[(create_definition,...)]
[table_options] [select_statement]
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
[() LIKE old_tbl_name []];

create_definition:
column_definition
  | [CONSTRAINT [symbol]] PRIMARY KEY [index_type] (index_col_name,...)
  | KEY [index_name] [index_type] (index_col_name,...)
  | INDEX [index_name] [index_type] (index_col_name,...)
  | [CONSTRAINT [symbol]] UNIQUE [INDEX]
[index_name] [index_type] (index_col_name,...)
  | [FULLTEXT|SPATIAL] [INDEX] [index_name] (index_col_name,...)
  | [CONSTRAINT [symbol]] FOREIGN KEY
[index_name] (index_col_name,...) [reference_definition]
  | CHECK (expr)

column_definition:
col_name type [NOT NULL | NULL] [DEFAULT default_value]
[AUTO_INCREMENT] [UNIQUE [KEY] | [PRIMARY] KEY]
[COMMENT 'string'] [reference_definition]

type:
TINYINT[(length)] [UNSIGNED] [ZEROFILL]
  | SMALLINT[(length)] [UNSIGNED] [ZEROFILL]
  | MEDIUMINT[(length)] [UNSIGNED] [ZEROFILL]
  | INT[(length)] [UNSIGNED] [ZEROFILL]
  | INTEGER[(length)] [UNSIGNED] [ZEROFILL]
  | BIGINT[(length)] [UNSIGNED] [ZEROFILL]
  | REAL[(length,decimals)] [UNSIGNED] [ZEROFILL]
  | DOUBLE[(length,decimals)] [UNSIGNED] [ZEROFILL]
  | FLOAT[(length,decimals)] [UNSIGNED] [ZEROFILL]
  | DECIMAL(length,decimals) [UNSIGNED] [ZEROFILL]
  | NUMERIC(length,decimals) [UNSIGNED] [ZEROFILL]
  | DATE
  | TIME
  | TIMESTAMP
  | DATETIME
  | CHAR(length) [BINARY | ASCII | UNICODE]
  | VARCHAR(length) [BINARY]
  | TINYBLOB
  | BLOB
  | MEDIUMBLOB
```

```
        │   LONGBLOB
        │   TINYTEXT [BINARY]
        │   TEXT [BINARY]
        │   MEDIUMTEXT [BINARY]
        │   LONGTEXT [BINARY]
        │   ENUM(value1,value2,value3,...)
        │   SET(value1,value2,value3,...)
        │   spatial_type

    index_col_name:
    col_name [(length)] [ASC | DESC]

    reference_definition:
    REFERENCES tbl_name [(index_col_name,...)]
    [MATCH FULL | MATCH PARTIAL | MATCH SIMPLE]
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

    reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION

    table_options: table_option [table_option] ...

    table_option:
    {ENGINE|TYPE} = engine_name
      │ AUTO_INCREMENT = value
      │ AVG_ROW_LENGTH = value
      │ [DEFAULT] CHARACTER SET charset_name [COLLATE collation_name]
      │ CHECKSUM = {0 | 1}
      │ COMMENT = 'string'
      │ MAX_ROWS = value
      │ MIN_ROWS = value
      │ PACK_KEYS = {0 | 1 | DEFAULT}
      │ PASSWORD = 'string'
      │ DELAY_KEY_WRITE = {0 | 1}
      │ ROW_FORMAT = {DEFAULT|DYNAMIC|FIXED|COMPRESSED|REDUNDANT|COMPACT}
      │ RAID_TYPE = { 1 | STRIPED | RAID0 }
    RAID_CHUNKS = value
    RAID_CHUNKSIZE = value
      │ UNION = (tbl_name[,tbl_name]...)
      │ INSERT_METHOD = { NO | FIRST | LAST }
      │ DATA DIRECTORY = 'absolute path to directory'
      │ INDEX DIRECTORY = 'absolute path to directory'

    select_statement:
    [IGNORE | REPLACE] [AS] SELECT ...    (Some legal select statement)
```

CREATE TABLE creates a table with the given name. You must have the CREATE privilege for the table.

Rules for allowable table names are given in Section 9.2, "Database, Table, Index, Column, and Alias Names". By default, the table is created in the current database. An error occurs if the table exists, if there is no current database, or if the database does not exist.

In MySQL 3.22 or later, the table name can be specified as *db_name*.*tbl_name* to create the table in a specific database. This works whether or not there is a current database. If you use quoted identifiers, quote the database and table names separately. For example, `mydb`.`mytbl` is legal, but `mydb.mytbl` is not.

From MySQL 3.23 on, you can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only to the current connection, and is dropped automatically when the connection is closed. This means that two different connections can use the same temporary table name without conflicting with each other or with an existing non-TEMPORARY table of the same name. (The existing table is hidden until the temporary table is dropped.) From MySQL 4.0.2 on, you must have the CREATE TEMPORARY TABLES privilege to be able to create temporary tables.

In MySQL 3.23 or later, you can use the keywords IF NOT EXISTS so that an error does not oc-

cur if the table exists. Note that there is no verification that the existing table has a structure identical to that indicated by the CREATE TABLE statement. Also, if you use IF NOT EXISTS in a CREATE TABLE ... SELECT statement, any records selected by the SELECT part are inserted regardless of whether the table already exists.

MySQL represents each table by an .frm table format (definition) file in the database directory. The storage engine for the table might create other files as well. In the case of MyISAM tables, the storage engine creates data and index files. Thus, for each MyISAM table tbl_name, there are three disk files:

File	Purpose
tbl_name.frm	Table format (definition) file
tbl_name.MYD	Data file
tbl_name.MYI	Index file

The files created by each storage engine to represent tables are described in Chapter 14, *MySQL Storage Engines and Table Types*.

For general information on the properties of the various column types, see Chapter 11, *Column Types*. For information about spatial column types, see Chapter 17, *Spatial Extensions in MySQL*.

- If neither NULL nor NOT NULL is specified, the column is treated as though NULL had been specified.

- An integer column can have the additional attribute AUTO_INCREMENT. When you insert a value of NULL (recommended) or 0 into an indexed AUTO_INCREMENT column, the column is set to the next sequence value. Typically this is value+1, where value is the largest value for the column currently in the table. AUTO_INCREMENT sequences begin with 1. Such a column must be defined as one of the integer types as described in Section 11.1.1, "Overview of Numeric Types". (The value 1.0 is **not** an integer.) See Section 23.2.3.34, "mysql_insert_id()".

  As of MySQL 4.1.1, specifying the NO_AUTO_VALUE_ON_ZERO flag for the --sql-mode server option or the sql_mode system variable allows you to store 0 in AUTO_INCREMENT columns as 0 without generating a new sequence value. See Section 5.3.1, "mysqld Command-Line Options".

  Note: There can be only one AUTO_INCREMENT column per table, it must be indexed, and it cannot have a DEFAULT value. As of MySQL 3.23, an AUTO_INCREMENT column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers "wrap" over from positive to negative and also to ensure that you don't accidentally get an AUTO_INCREMENT column that contains 0.

  For MyISAM and BDB tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. See Section 3.6.9, "Using AUTO_INCREMENT".

  To make MySQL compatible with some ODBC applications, you can find the AUTO_INCREMENT value for the last inserted row with the following query:

  ```
  SELECT * FROM tbl_name WHERE auto_col IS NULL
  ```

- As of MySQL 4.1, character column definitions can include a CHARACTER SET attribute to specify the character set and, optionally, a collation for the column. For details, see Chapter 10, *Character Set Support*. CHARSET is a synonym for CHARACTER SET.

  ```
  CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
  ```

  Also as of 4.1, MySQL interprets length specifications in character column definitions in characters. (Earlier versions interpret them in bytes.)

- `NULL` values are handled differently for `TIMESTAMP` columns than for other column types. Before MySQL 4.1.6, you cannot store a literal `NULL` in a `TIMESTAMP` column; setting the column to `NULL` sets it to the current date and time. Because `TIMESTAMP` columns behave this way, the `NULL` and `NOT NULL` attributes do not apply in the normal way and are ignored if you specify them. On the other hand, to make it easier for MySQL clients to use `TIMESTAMP` columns, the server reports that such columns can be assigned `NULL` values (which is true), even though `TIMESTAMP` never actually contains a `NULL` value. You can see this when you use `DESCRIBE` *tbl_name* to get a description of your table.

  Note that setting a `TIMESTAMP` column to `0` is not the same as setting it to `NULL`, because `0` is a valid `TIMESTAMP` value.

-
  The `DEFAULT` clause specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for a `TIMESTAMP` column as of MySQL 4.1.2. See Section 11.3.1.2, "`TIMESTAMP` Properties as of MySQL 4.1".

  Prior to MySQL 5.0.2, if a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

  If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

  If the column cannot take `NULL` as the value, MySQL defines the column with an explicit `DEFAULT` clause, using the implicit default value for the column data type. Implicit defaults are defined as follows:

  - For numeric types other than those declared with the `AUTO_INCREMENT` attribute, the default is `0`. For an `AUTO_INCREMENT` column, the default value is the next value in the sequence.

  - For date and time types other than `TIMESTAMP`, the default is the appropriate "zero" value for the type. For the first `TIMESTAMP` column in a table, the default value is the current date and time. See Section 11.3, "Date and Time Types".

  - For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

  `BLOB` and `TEXT` columns cannot be assigned a default value.

  As of MySQL 5.0.2, if a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

  If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause. This is the same as before 5.0.2.

  If the column cannot take `NULL` as the value, MySQL defines the column with no explicit `DEFAULT` clause. For data entry, if an `INSERT` or `REPLACE` statement includes no value for the column, MySQL handles the column according to the SQL mode in effect at the time:

  - If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

  - If strict mode is enabled, an error occurs for transactional tables and the statement is rolled back. For non-transactional tables, an error occurs, but if this happens for the the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.

  Suppose that a table `t` is defined as follows:

  ```
  CREATE TABLE t (i INT NOT NULL);
  ```

In this case, i has no explicit default, so in strict mode all of the following statements produce an error in strict mode and no row is inserted. For non strict mode, only the third statement produces an error; the implicit default is inserted for the first two, but the third fails because `DE-FAULT(i)` cannot produce a value:

```
INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));
```

See Section 5.3.2, "The Server SQL Mode".

For a given table, you can use the `SHOW CREATE TABLE` statement to see which columns have an explicit `DEFAULT` clause.

•
   A comment for a column can be specified with the `COMMENT` option. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements. This option is operational as of MySQL 4.1. (It is allowed but ignored in earlier versions.)

• From MySQL 4.1.0 on, the attribute `SERIAL` can be used as an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

• `KEY` is normally a synonym for `INDEX`. From MySQL 4.1, the key attribute `PRIMARY KEY` can also be specified as just `KEY` when given in a column definition. This was implemented for compatibility with other database systems.

• In MySQL, a `UNIQUE` index is one in which all values in the index must be distinct. An error occurs if you try to add a new row with a key that matches an existing row. The exception to this is that if a column in the index is allowed to contain `NULL` values, it can contain multiple `NULL` values. This exception does not apply to `BDB` tables, for which an indexed column allows only a single `NULL`.

•
   A `PRIMARY KEY` is a unique `KEY` where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. If you don't have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

• In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the non-unique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.

• A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(index_col_name, ...)` clause.

• If a `PRIMARY KEY` or `UNIQUE` index consists of only one column that has an integer type, you can also refer to the column as `_rowid` in `SELECT` statements (new in MySQL 3.23.11).

• In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you don't assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2`, `_3`, `...`) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See Section 13.5.4.11, "`SHOW INDEX` Syntax".

• From MySQL 4.1.0 on, some storage engines allow you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`.

Example:

```
CREATE TABLE lookup
```

```
                    (id INT, INDEX USING BTREE (id))
                    ENGINE = MEMORY;
```

For details about `USING`, see Section 13.1.4, "`CREATE INDEX` Syntax".

For more information about how MySQL uses indexes, see Section 7.4.5, "How MySQL Uses Indexes".

*   Only the `MyISAM`, `InnoDB`, `BDB`, and (as of MySQL 4.0.2) `MEMORY` storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.

*   With `col_name(length)` syntax in an index specification, you can create an index that uses only the first `length` characters of a `CHAR` or `VARCHAR` column. Indexing only a prefix of column values like this can make the index file much smaller. See Section 7.4.3, "Column Indexes".

    The `MyISAM` and (as of MySQL 4.0.14) `InnoDB` storage engines also support indexing on `BLOB` and `TEXT` columns. When indexing a `BLOB` or `TEXT` column, you *must* specify a prefix length for the index. For example:

    ```
                    CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
    ```

    Prefixes can be up to 255 bytes long (or 1000 bytes for `MyISAM` and `InnoDB` tables as of MySQL 4.1.2). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters. Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

*   An `index_col_name` specification can end with `ASC` or `DESC`. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently they are parsed but ignored; index values are always stored in ascending order.

*   When you use `ORDER BY` or `GROUP BY` with a `TEXT` or `BLOB` column, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable. See Section 11.4.3, "The `BLOB` and `TEXT` Types".

*   In MySQL 3.23.23 or later, you can create special `FULLTEXT` indexes. They are used for full-text search. Only the `MyISAM` table type supports `FULLTEXT` indexes. They can be created only from `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; partial indexing is not supported and any prefix length is ignored if specified. See Section 12.7, "Full-Text Search Functions" for details of operation.

*   In MySQL 4.1 or later, you can create `SPATIAL` indexes on spatial column types. Spatial types are supported only for `MyISAM` tables and indexed columns must be declared as `NOT NULL`. See Chapter 17, *Spatial Extensions in MySQL*.

*   In MySQL 3.23.44 or later, `InnoDB` tables support checking of foreign key constraints. See Chapter 15, *The InnoDB Storage Engine*. Note that the `FOREIGN KEY` syntax in `InnoDB` is more restrictive than the syntax presented for the `CREATE TABLE` statement at the beginning of this section: The columns of the referenced table must always be explicitly named. `InnoDB` supports both `ON DELETE` and `ON UPDATE` actions on foreign keys as of MySQL 3.23.50 and 4.0.8, respectively. For the precise syntax, see Section 15.7.4, "`FOREIGN KEY` Constraints".

    For other storage engines, MySQL Server parses the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements, but without further action being taken. The `CHECK` clause is parsed but ignored by all storage engines. See Section 1.8.5.5, "Foreign Keys".

*   For `MyISAM` and `ISAM` tables, each `NULL` column takes one bit extra, rounded up to the nearest byte. The maximum record length in bytes can be calculated as follows:

```
row length = 1
+ (sum of column lengths)
+ (number of NULL columns + delete_flag + 7)/8
+ (number of variable-length columns)
```

`delete_flag` is 1 for tables with static record format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. `delete_flag` is 0 for dynamic tables because the flag is stored in the dynamic row header.

These calculations do not apply for `InnoDB` tables, for which storage size is no different for `NULL` columns than for `NOT NULL` columns.

The `table_options` part of the `CREATE TABLE` syntax can be used in MySQL 3.23 and above.

The `ENGINE` and `TYPE` options specify the storage engine for the table. `ENGINE` was added in MySQL 4.0.18 (for 4.0) and 4.1.2 (for 4.1). It is the preferred option name as of those versions, and `TYPE` has become deprecated. `TYPE` is supported throughout the 4.x series, but likely will be removed in MySQL 5.1.

The `ENGINE` and `TYPE` options take the following values:

Storage Engine	Description
ARCHIVE	The archving storage engine. See Section 14.7, "The `ARCHIVE` Storage Engine".
BDB	Transaction-safe tables with page locking. See Section 14.4, "The `BDB` (`BerkeleyDB`) Storage Engine".
BerkeleyDB	An alias for `BDB`.
CSV	Tables that store rows in comma-separated values format. See Section 14.8, "The `CSV` Storage Engine".
EXAMPLE	An example engine. See Section 14.5, "The `EXAMPLE` Storage Engine".
FEDERATED	Storage engine that accesses remote tables. See Section 14.6, "The `FEDERATED` Storage Engine".
HEAP	The data for this table is stored only in memory. See Section 14.3, "The `MEMORY` (`HEAP`) Storage Engine".
ISAM	The original MySQL storage engine. See Section 14.10, "The `ISAM` Storage Engine".
InnoDB	Transaction-safe tables with row locking and foreign keys. See Chapter 15, *The `InnoDB` Storage Engine*.
MEMORY	An alias for `HEAP`. (Actually, as of MySQL 4.1, `MEMORY` is the preferred term.)
MERGE	A collection of `MyISAM` tables used as one table. See Section 14.2, "The `MERGE` Storage Engine".
MRG_MyISAM	An alias for `MERGE`.
MyISAM	The binary portable storage engine that is the improved replacement for `ISAM`. See Section 14.1, "The `MyISAM` Storage Engine".
NDB	Alias for `NDBCLUSTER`.
NDBCLUSTER	Clustered, fault-tolerant, memory-based tables. See Chapter 16, *MySQL Cluster*.

See Chapter 14, *MySQL Storage Engines and Table Types*.

If a storage engine is specified that is not available, MySQL uses `MyISAM` instead. For example, if a

table definition includes the `ENGINE=BDB` option but the MySQL server does not support `BDB` tables, the table is created as a `MyISAM` table. This makes it possible to have a replication setup where you have transactional tables on the master but tables created on the slave are non-transactional (to get more speed). In MySQL 4.1.1, a warning occurs if the storage engine specification is not honored.

The other table options are used to optimize the behavior of the table. In most cases, you don't have to specify any of them. The options work for all storage engines unless otherwise indicated:

- `AUTO_INCREMENT`

  The initial `AUTO_INCREMENT` value for the table. This works for `MyISAM` only, for `MEMORY` as of MySQL 4.1, and for `InnoDB` as of MySQL 5.0.3. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a dummy row with a value one less than the desired value after creating the table, and then delete the dummy row.

  For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE` *tbl_name* `AUTO_INCREMENT = ` *n* to reset the `AUTO_INCREMENT` value.

- `AVG_ROW_LENGTH`

  An approximation of the average row length for your table. You need to set this only for large tables with variable-size records.

  When you create a `MyISAM` table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for a table is 65,536TB of data (4GB before MySQL 5.0.6). (If your operating system does not support files that large, table sizes are constrained by the operating system limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `my-isam_data_pointer_size` system variable, which was added in MySQL 4.1.2. (See Section 5.3.3, "Server System Variables".) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you may increase the default pointer size by setting this variable.

- `[DEFAULT] CHARACTER SET`

  Specify a default character set for the table. `CHARSET` is a synonym

  for `CHARACTER SET`.

- `COLLATE`

  Specify a default collation for the table.

- `CHECKSUM`

  Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. (`MyISAM` only.)

- `COMMENT`

  A comment for your table, up to 60 characters long.

- `MAX_ROWS`

  The maximum number of rows you plan to store in the table. This is not a hard limit, but rather an indicator that the table must be able to store at least this many rows.

- `MIN_ROWS`

The minimum number of rows you plan to store in the table.

- PACK_KEYS

  Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to DEFAULT (MySQL 4.0) tells the storage engine to only pack long CHAR/VARCHAR columns. (MyISAM and ISAM only.)

  If you don't use PACK_KEYS, the default is to only pack strings, not numbers. If you use PACK_KEYS=1, numbers are packed as well.

  When packing binary number keys, MySQL uses prefix compression:

  - Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.

  - The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

  This means that if you have many equal keys on two consecutive rows, all following "same" keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes storage_size_for_key + pointer_size (where the pointer size is usually 4). Conversely, you get a big benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key isn't a key that can have NULL values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is NULL.)

- PASSWORD

  Encrypt the .frm file with a password. This option doesn't do anything in the standard MySQL version.

- DELAY_KEY_WRITE

  Set this to 1 if you want to delay key updates for the table until the table is closed. (MyISAM only.)

- ROW_FORMAT

  Defines how the rows should be stored. Currently this option works only with MyISAM tables. The option value can FIXED or DYNAMIC for static or variable-length row format. myisam-pack sets the type to COMPRESSED. See Section 14.1.3, "MyISAM Table Storage Formats".

  Starting with MySQL/InnoDB-5.0.3, InnoDB records are stored in a more compact format (ROW_FORMAT=COMPACT) by default. The old format can be requested by specifying ROW_FORMAT=REDUNDANT.

-
  RAID_TYPE

  Note: This information applies only before MySQL 5.0. RAID support has been removed as of MySQL 5.0.

  The RAID_TYPE option can help you to exceed the 2GB/4GB limit for the MyISAM data file (not the index file) on operating systems that don't support big files. This option is unnecessary and not recommended for filesystems that support big files.

  You can get more speed from the I/O bottleneck by putting RAID directories on different physical disks. The only allowed RAID_TYPE is STRIPED. 1 and RAID0 are aliases for STRIPED.

  If you specify the RAID_TYPE option for a MyISAM table, specify the RAID_CHUNKS and RAID_CHUNKSIZE options as well. The maximum RAID_CHUNKS value is 255. MyISAM

creates RAID_CHUNKS subdirectories named 00, 01, 02, ... 09, 0a, 0b, ... in the database dir-
ectory. In each of these directories, MyISAM creates a file tbl_name.MYD. When writing data
to the data file, the RAID handler maps the first RAID_CHUNKSIZE*1024 bytes to the first
file, the next RAID_CHUNKSIZE*1024 bytes to the next file, and so on.

RAID_TYPE works on any operating system, as long as you have built MySQL with the --
-with-raid option to configure. To determine whether a server supports RAID tables,
use SHOW VARIABLES LIKE 'have_raid' to see whether the variable value is YES.

- UNION

  UNION is used when you want to use a collection of identical tables as one. This works only
  with MERGE tables. See Section 14.2, "The MERGE Storage Engine".

  For the moment, you must have SELECT, UPDATE, and DELETE privileges for the tables you
  map to a MERGE table. Originally, all used tables had to be in the same database as the MERGE
  table itself. This restriction has been lifted as of MySQL 4.1.1.

- INSERT_METHOD

  If you want to insert data in a MERGE table, you have to specify with INSERT_METHOD into
  which table the row should be inserted. INSERT_METHOD is an option useful for MERGE tables
  only. Use a value of FIRST or LAST to have inserts go to the first or last table, or a value of NO
  to prevent inserts. This option was introduced in MySQL 4.0.0. See Section 14.2, "The MERGE
  Storage Engine".

- DATA DIRECTORY, INDEX DIRECTORY

  By using DATA DIRECTORY='directory' or INDEX DIRECTORY='directory' you
  can specify where the MyISAM storage engine should put a table's data file and index file. Note
  that the directory should be a full path to the directory (not a relative path).

  These options work only for MyISAM tables from MySQL 4.0 on, when you are not using the --
  -skip-symbolic-links option. Your operating system must also have a working, thread-
  safe realpath() call. See Section 7.6.1.2, "Using Symbolic Links for Tables on Unix".

As of MySQL 3.23, you can create one table from another by adding a SELECT statement at the end
of the CREATE TABLE statement:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the SELECT. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
    ->        PRIMARY KEY (a), KEY(b))
    ->        TYPE=MyISAM SELECT b,c FROM test2;
```

This creates a MyISAM table with three columns, a, b, and c. Notice that the columns from the SE-
LECT statement are appended to the right side of the table, not overlapped onto it. Take the follow-
ing example:

```
mysql> SELECT * FROM foo;
+---+
| n |
+---+
| 1 |
+---+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0
```

```
mysql> SELECT * FROM bar;
+------+---+
| m    | n |
+------+---+
| NULL | 1 |
+------+---+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of column types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns.

When creating a table with `CREATE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
SELECT artist.name, COUNT(work.artist_id) AS number_of_works
FROM artist LEFT JOIN work ON artist.id = work.artist_id
GROUP BY artist.id;
```

As of MySQL 4.1, you can explicitly specify the type for a generated column:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

In MySQL 4.1, you can also use `LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes the original table has:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

`CREATE TABLE ... LIKE` does not copy any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle records that duplicate unique key values. With `IGNORE`, new records that duplicate an existing record on a unique key value are discarded. With `REPLACE`, new records replace records that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error.

To ensure that the update log/binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts during `CREATE TABLE ... SELECT`.

13.1.5.1. Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a `CREATE TABLE` or `ALTER TABLE` statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

Possible data type changes are given in the following list. These occur prior to MySQL 5.0.3. (As of 5.0.3 an error occurs if a column cannot be created using the specified data type.)

- VARCHAR columns with a length less than four are changed to CHAR.

- If any column in a table has a variable length, the entire row becomes variable-length as a result. Therefore, if a table contains any variable-length columns (VARCHAR, TEXT, or BLOB), all CHAR columns longer than three characters are changed to VARCHAR columns. This doesn't affect how you use the columns in any way; in MySQL, VARCHAR is just a different way to store characters. MySQL performs this conversion because it saves space and makes table operations faster. See Chapter 14, *MySQL Storage Engines and Table Types*.

- From MySQL 4.1.0 to MySQL 5.0.2, a CHAR or VARCHAR column with a length specification greater than 255 is converted to the smallest TEXT type that can hold values of the given length. For example, VARCHAR(500) is converted to TEXT, and VARCHAR(200000) is converted to MEDIUMTEXT. Note that this conversion results in a change in behavior with regard to treatment of trailing spaces.

  Similar conversions occur for BINARY and VARBINARY, except that they are converted to a BLOB type.

  From MySQL 5.0.3 on, CHAR and BINARY columns with a length specification greater than 255 are not silently converted. Instead, an error occurs. From MySQL 5.0.6 on, silent conversion of VARCHAR and VARBINARY columns with a length specification greater than 65,535 does not occur if strict SQL mode is enabled. Instead, an error occurs.

- For a specification of DECIMAL(*M*,*D*), if *M* is not larger than *D*, it is adjusted upward. For example, DECIMAL(10,10) becomes DECIMAL(11,10).

Other silent column specification changes include changes to attribute or index specifications:

- TIMESTAMP display sizes are discarded from MySQL 4.1 on, due to changes made to the TIMESTAMP column type in that version. Before MySQL 4.1, TIMESTAMP display sizes must be even and in the range from 2 to 14. If you specify a display size of 0 or greater than 14, the size is coerced to 14. Odd-valued sizes in the range from 1 to 13 are coerced to the next higher even number.

- Before MySQL 4.1.6, you cannot store a literal NULL in a TIMESTAMP column; setting it to NULL sets it to the current date and time. Because TIMESTAMP columns behave this way, the NULL and NOT NULL attributes do not apply in the normal way and are ignored if you specify them. DESCRIBE *tbl_name* always reports that a TIMESTAMP column can be assigned NULL values.

- Columns that are part of a PRIMARY KEY are made NOT NULL even if not declared that way.

- Starting from MySQL 3.23.51, trailing spaces are automatically deleted from ENUM and SET member values when the table is created.

- MySQL maps certain column types used by other SQL database vendors to MySQL types. See Section 11.7, "Using Column Types from Other Database Engines".

- If you include a USING clause to specify an index type that is not legal for a storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

To see whether MySQL used a column type other than the one you specified, issue a DESCRIBE or SHOW CREATE TABLE statement after creating or altering your table.

Certain other column type changes can occur if you compress a table using myisampack. See Section 14.1.3.3, "Compressed Table Characteristics".

13.1.6. DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be *very* careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database.

In MySQL 3.22 or later, you can use the keywords `IF EXISTS` to prevent an error from occurring if the database doesn't exist.

`DROP SCHEMA` can be used as of MySQL 5.0.2.

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

As of MySQL 4.1.2, `DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with these extensions:

.BAK	.DAT	.HSH	.ISD
.ISM	.ISM	.MRG	.MYD
.MYI	.db	.frm	

- All subdirectories with names that consist of two hex digits `00-ff`. These are subdirectories used for `RAID` tables. (These directories are not removed as of MySQL 5.0, when support for `RAID` tables was removed. You should convert your `RAID` tables and remove these directories manually before upgrading to MySQL 5.0. See Section 2.10.2, "Upgrading from Version 4.1 to 5.0".)

- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

You can also drop databases with `mysqladmin`. See Section 8.4, "mysqladmin — Client for Administering a MySQL Server".

13.1.7. `DROP INDEX` Syntax

```
DROP INDEX index_name ON tbl_name
```

`DROP INDEX` drops the index named *index_name* from the table *tbl_name*. In MySQL 3.22 or later, `DROP INDEX` is mapped to an `ALTER TABLE` statement to drop the index. See Section 13.1.2, "ALTER TABLE Syntax". `DROP INDEX` doesn't do anything prior to MySQL 3.22.

13.1.8. `DROP TABLE` Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
    tbl_name [, tbl_name] ...
    [RESTRICT | CASCADE]
```

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table. All table data and the table definition are *removed*, so *be careful* with this statement!

In MySQL 3.22 or later, you can use the keywords `IF EXISTS` to prevent an error from occurring for tables that don't exist. As of MySQL 4.1, a `NOTE` is generated for each non-existent table when using `IF EXISTS`. See Section 13.5.4.22, "`SHOW WARNINGS` Syntax".

`RESTRICT` and `CASCADE` are allowed to make porting easier. For the moment, they do nothing.

Note: `DROP TABLE` automatically commits the current active transaction, unless you are using MySQL 4.1 or higher and the `TEMPORARY` keyword.

The `TEMPORARY` keyword is ignored in MySQL 4.0. As of 4.1, it has the following effect:

- The statement drops only `TEMPORARY` tables.

- The statement doesn't end a running transaction.

- No access rights are checked. (A `TEMPORARY` table is visible only to the client that created it, so no check is necessary.)

Using `TEMPORARY` is a good way to ensure that you don't accidentally drop a non-`TEMPORARY` table.

13.1.9. `RENAME TABLE` Syntax

```
RENAME TABLE tbl_name TO new_tbl_name
[, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables. It was added in MySQL 3.23.23.

The rename operation is done atomically, which means that no other thread can access any of the tables while the rename is running. For example, if you have an existing table `old_table`, you can create another table `new_table` that has the same structure but is empty, and then replace the existing table with the empty one as follows:

```
CREATE TABLE new_table (...);
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that no table named `tmp_table` currently exists):

```
RENAME TABLE old_table TO tmp_table,
new_table TO old_table,
tmp_table TO new_table;
```

As long as two databases are on the same filesystem you can also rename a table to move it from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

When you execute `RENAME`, you can't have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to get everything back to the original state.

13.2. Data Manipulation Statements

13.2.1. `DELETE` Syntax

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
       [WHERE where_definition]
       [ORDER BY ...]
       [LIMIT row_count]
```

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
       tbl_name[.*] [, tbl_name[.*] ...]
       FROM table_references
       [WHERE where_definition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
       FROM tbl_name[.*] [, tbl_name[.*] ...]
       USING table_references
       [WHERE where_definition]
```

`DELETE` deletes rows from `tbl_name` that satisfy the condition given by `where_definition`, and returns the number of records deleted.

If you issue a `DELETE` statement with no `WHERE` clause, all rows are deleted. A faster way to do this, when you don't want to know the number of deleted rows, is to use `TRUNCATE TABLE`. See Section 13.2.9, "`TRUNCATE` Syntax".

In MySQL 3.23, `DELETE` without a `WHERE` clause returns zero as the number of affected records.

In MySQL 3.23, if you really want to know how many records are deleted when you are deleting all rows, and are willing to suffer a speed penalty, you can use a `DELETE` statement that includes a `WHERE` clause with an expression that is true for every row. For example:

```
mysql> DELETE FROM tbl_name WHERE 1>0;
```

This is much slower than `TRUNCATE tbl_name`, because it deletes rows one at a time.

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is reused for an `ISAM` or `BDB` table, but not for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE`) in `AUTOCOMMIT` mode, the sequence starts over for all table types except for `InnoDB` and (as of MySQL 4.0) `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, discussed in Section 15.7.3, "How an `AUTO_INCREMENT` Column Works in `InnoDB`".

For `MyISAM` and `BDB` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See Section 3.6.9, "Using `AUTO_INCREMENT`".

The `DELETE` statement supports the following modifiers:

- If you specify the `LOW_PRIORITY` keyword, execution of the `DELETE` is delayed until no other clients are reading from the table.

- For `MyISAM` tables, if you specify the `QUICK` keyword, the storage engine does not merge index leaves during delete, which may speed up certain kind of deletes.

- The `IGNORE` keyword causes MySQL to ignore all errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are

ignored due to the use of this option are returned as warnings. This option first appeared in MySQL 4.1.1.

The speed of delete operations may also be affected by factors discussed in Section 7.2.18, "Speed of DELETE Statements".

In MyISAM tables, deleted records are maintained in a linked list and subsequent INSERT operations reuse old record positions. To reclaim unused space and reduce file sizes, use the OPTIMIZE TABLE statement or the myisamchk utility to reorganize tables. OPTIMIZE TABLE is easier, but myisamchk is faster. See Section 13.5.2.5, "OPTIMIZE TABLE Syntax" and Section 5.8.5.9, "Table Optimization".

The QUICK modifier affects whether index leaves are merged for delete operations. DELETE QUICK is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of QUICK can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed AUTO_INCREMENT column.

2. Insert many records into the table. Each insert results in an index values that is added to the high end of the index.

3. Delete a block of records at the low end of the column range using DELETE QUICK.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of QUICK. They remain underfilled when new inserts occur, because new records does not have index values in the deleted range. Furthermore, they remain underfilled even if you later use DELETE without QUICK, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, you can use OPTIMIZE TABLE.

If you are going to delete many rows from a table, it might be faster to use DELETE QUICK followed by OPTIMIZE TABLE. This rebuilds the index rather than performing many index block merge operations.

The MySQL-specific LIMIT *row_count* option to DELETE tells the server the maximum number of rows to be deleted before control is returned to the client. This can be used to ensure that a specific DELETE statement doesn't take too much time. You can simply repeat the DELETE statement until the number of affected rows is less than the LIMIT value.

If the DELETE statement includes an ORDER BY clause, the rows are deleted in the order specified by the clause. This is really useful only in conjunction with LIMIT. For example, the following statement finds rows matching the WHERE clause, sorts them in timestamp order, and deletes the first (oldest) one:

```
DELETE FROM somelog
WHERE user = 'jcole'
ORDER BY timestamp
LIMIT 1
```

ORDER BY can be used with DELETE beginning with MySQL 4.0.0.

From MySQL 4.0, you can specify multiple tables in the DELETE statement to delete rows from one or more tables depending on a particular condition in multiple tables. However, you cannot use ORDER BY or LIMIT in a multiple-table DELETE.

The first multiple-table DELETE syntax is supported starting from MySQL 4.0.0. The second is sup-

ported starting from MySQL 4.0.2. The `table_references` part lists the tables involved in the join. Its syntax is described in Section 13.2.7.1, "JOIN Syntax".

For the first syntax, only matching rows from the tables listed before the FROM clause are deleted. For the second syntax, only matching rows from the tables listed in the FROM clause (before the USING clause) are deleted. The effect is that you can delete rows from many tables at the same time and also have additional tables that are used for searching:

```
DELETE t1, t2 FROM t1, t2, t3 WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1, t2, t3 WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three files when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The examples show inner joins using the comma operator, but multiple-table DELETE statements can use any type of join allowed in SELECT statements, such as LEFT JOIN.

The syntax allows `.*` after the table names for compatibility with `Access`.

If you use a multiple-table DELETE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, delete from a single table and rely on the ON DELETE capabilities that InnoDB provides to cause the other tables to be modified accordingly.

Note: In MySQL 4.0, you should refer to the table names to be deleted with the true table name. In MySQL 4.1, you must use the alias (if one was given) when referring to a table name:

In MySQL 4.0:

```
DELETE test FROM test AS t1, test2 WHERE ...
```

In MySQL 4.1:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

The reason we didn't make this change in 4.0 was to avoid breaking any old 4.0 applications that were using the old syntax.

Cross-database deletes are supported for multiple-table deletes, but in this case, you must refer to the tables without using aliases. For example:

```
DELETE test1.tmp1, test2.tmp2 FROM test1.tmp1, test2.tmp2 WHERE ...
```

Currently, you cannot delete from a table and select from the same table in a subquery.

13.2.2. DO Syntax

```
DO expr [, expr] ...
```

DO executes the expressions but doesn't return any results. This is shorthand for SELECT *expr*, `...`, but has the advantage that it's slightly faster when you don't care about the result.

DO is useful mainly with functions that have side effects, such as RELEASE_LOCK().

DO was added in MySQL 3.23.47.

13.2.3. `HANDLER` Syntax

```
HANDLER tbl_name OPEN [ AS alias ]
HANDLER tbl_name READ index_name { = | >= | <= | < } (value1,value2,...)
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name CLOSE
```

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for `MyISAM` tables as MySQL 4.0.0 and `InnoDB` tables as of MySQL 4.0.3.

The `HANDLER ... OPEN` statement opens a table, making it accessible via subsequent `HANDLER ... READ` statements. This table object is not shared by other threads and is not closed until the thread calls `HANDLER ... CLOSE` or the thread terminates. If you open the table using an alias, further references to the table with other `HANDLER` statements must use the alias rather than the table name.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... index_name = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... index_name = (col_a_val,col_b_val) ...
HANDLER ... index_name = (col_a_val) ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See Section 13.2.7, "`SELECT` Syntax".

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

Note: To use the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier `` `PRIMARY` ``:

```
HANDLER tbl_name READ `PRIMARY` > (...);
```

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does *not* take a snapshot of the table, and does *not* lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by this or any other thread) and these modifications might appear only partially in `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

• `HANDLER` is faster than `SELECT`:

- A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for the following `HANDLER` statements for the table; it need not be reinitialized for each one.

- There is less parsing involved.

- There is no optimizer or query-checking overhead.

- The table doesn't have to be locked between two handler requests.

- The handler interface doesn't have to provide a consistent look of the data (for example, dirty reads are allowed), so the storage engine can use optimizations that `SELECT` doesn't normally allow.

- `HANDLER` makes it much easier to port applications that use an `ISAM`-like interface to MySQL.

- `HANDLER` allows you to traverse a database in a manner that is not easy (or perhaps even impossible) to do with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

13.2.4. `INSERT` Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [(col_name,...)]
    VALUES ({expr | DEFAULT},...),(...),...
    [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    SET col_name={expr | DEFAULT}, ...
    [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [(col_name,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. The `INSERT ... VALUES` form with multiple value lists is supported in MySQL 3.22.5 or later. The `INSERT ... SET` syntax is supported in MySQL 3.22.10 or later. `INSERT ... SELECT` is discussed further in See Section 13.2.4.1, "`INSERT ... SELECT` Syntax".

`tbl_name` is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- The column name list or the `SET` clause indicates the columns explicitly.

- If you do not specify the column list for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided in the `VALUES()` list or by the `SELECT`. If you don't know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.

Column values can be given in several ways:

-
  If you are not running in strict mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that doesn't name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 13.1.5, "CREATE TABLE Syntax". See Section 1.8.6.2, "Constraints on Invalid Data".

  If you want INSERT statements to generate an error unless you explicitly specify values for all columns that don't have a default value, you should use STRICT mode. See Section 5.3.2, "The Server SQL Mode".

- You can use the keyword DEFAULT to explicitly set a column to its default value. (New in MySQL 4.0.3.) This makes it easier to write INSERT statements that assign values to all but a few columns, because it allows you to avoid writing an incomplete VALUES list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the VALUES list.

  As of MySQL 4.1.0, you can use DEFAULT(*col_name*) as a more general form that can be used in expressions to produce a column's default value.

- If both the column list and the VALUES list are empty, INSERT creates a row with each column set to its default value:

  ```
  mysql> INSERT INTO tbl_name () VALUES();
  ```

  In STRICT mode you will get an error if a column doesn't have a default value. In not strict mode, MySQL will use the implicit default value for any column with a not defined default value.

- You can specify an expression *expr* to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string '1999.0e-2' into an INT, FLOAT, DECIMAL(10,6), or YEAR column results in the values 1999, 19.9921, 19.992100, and 1999. The reason the value stored in the INT and YEAR columns is 1999 is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string as a valid floating-point value.

  An expression *expr* can refer to any column that was set earlier in a value list. For example, you can do this because the value for col2 refers to col1, which has previously been assigned:

  ```
  mysql> INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
  ```

  But you cannot do this because the value for col1 refers to col2, which is assigned after col1:

  ```
  mysql> INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
  ```

  One exception involves columns that contain AUTO_INCREMENT values. Because the AUTO_INCREMENT value is generated after other value assignments, any reference to an AUTO_INCREMENT column in the assignment returns a 0.

The INSERT statement supports the following modifiers:

- If you specify the DELAYED keyword, the server puts the row or rows to be inserted into a buffer, and the client issuing the INSERT DELAYED statement then can continue on. If the table is busy, the server holds the rows. When the table becomes free, it begins inserting rows, checking periodically to see whether there are new read requests for the table. If there are, the delayed row

queue is suspended until the table becomes free again. See Section 13.2.4.2, "INSERT DELAYED Syntax". DELAYED was added in MySQL 3.22.5.

- If you specify the LOW_PRIORITY keyword, execution of the INSERT is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the INSERT LOW_PRIORITY statement is waiting. It is possible, therefore, for a client that issues an INSERT LOW_PRIORITY statement to wait for a very long time (or even forever) in a read-heavy environment. (This is in contrast to INSERT DELAYED, which lets the client continue at once.) See Section 13.2.4.2, "INSERT DELAYED Syntax". Note that LOW_PRIORITY should normally not be used with MyISAM tables because doing so disables concurrent inserts. See Section 14.1, "The MyISAM Storage Engine". LOW_PRIORITY was added in MySQL 3.22.5.

- If you specify the HIGH_PRIORITY keyword, it overrides the effect of the --low-priority-updates option if the server was started with that option. It also causes concurrent inserts not to be used. HIGH_PRIORITY was added in MySQL 3.23.11.

- The rows-affected value for an INSERT can be obtained using the mysql_affected_rows() C API function. See Section 23.2.3.1, "mysql_affected_rows()".

- If you specify the IGNORE keyword in an INSERT statement, errors that occur while executing the statement are treated as warnings instead. For example, without IGNORE, a row that duplicates an existing UNIQUE index or PRIMARY KEY value in the table causes a duplicate-key error and the statement is aborted. With IGNORE, the error is ignored and the row is not inserted. Data conversions that would trigger errors abort the statement if IGNORE is not specified. With IGNORE, invalid values are adjusted to the closest value values and inserted; warnings are produced but the statement does not abort. You can determine with the mysql_info() C API function how many rows were inserted into the table.

If you specify the ON DUPLICATE KEY UPDATE clause (new in MySQL 4.1.0), and a row is inserted that would cause a duplicate value in a UNIQUE index or PRIMARY KEY, an UPDATE of the old row is performed. For example, if column a is declared as UNIQUE and contains the value 1, the following two statements have identical effect:

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3)
    -> ON DUPLICATE KEY UPDATE c=c+1;

mysql> UPDATE table SET c=c+1 WHERE a=1;
```

The rows-affected value is 1 if the row is inserted as a new record and 2 if an existing record is updated.

Note: If column b is unique too, the INSERT would be equivalent to this UPDATE statement instead:

```
mysql> UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If a=1 OR b=2 matches several rows, only *one* row is updated! In general, you should try to avoid using the ON DUPLICATE KEY clause on tables with multiple UNIQUE keys.

As of MySQL 4.1.1, you can use the VALUES(col_name) function in the UPDATE clause to refer to column values from the INSERT part of the INSERT ... UPDATE statement. In other words, VALUES(col_name) in the UPDATE clause refers to the value of *col_name* that would be inserted if no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The VALUES() function is meaningful only in INSERT ... UPDATE statements and returns NULL otherwise.

Example:

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
```

```
    -> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3)
    -> ON DUPLICATE KEY UPDATE c=3;
mysql> INSERT INTO table (a,b,c) VALUES (4,5,6)
    -> ON DUPLICATE KEY UPDATE c=9;
```

When you use `ON DUPLICATE KEY UPDATE`, the `DELAYED` option is ignored.

You can find the value used for an `AUTO_INCREMENT` column by using the `LAST_INSERT_ID()` function. From within the C API, use the `mysql_insert_id()` function. However, note that the two functions do not behave quite identically under all circumstances. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in Section 12.9.3, "Information Functions" and Section 23.2.3.34, "`mysql_insert_id()`".

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted. `Duplicates` can be non-zero.) `Duplicates` indicates the number of rows that couldn't be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is `0` for numeric types, the empty string (`''`) for string types, and the "zero" value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as `'10.34 a'` to a numeric column. The trailing non-numeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to `0`.

- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.

- Inserting a value into a date or time column that is illegal for the column type. The column is set to the appropriate zero value for the type.

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See Section 23.2.3.32, "`mysql_info()`".

13.2.4.1. `INSERT ... SELECT` Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [(col_name,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With `INSERT  ...  SELECT`, you can quickly insert many rows into a table from one or many tables.

For example:

```
INSERT INTO tbl_temp2 (fld_id)
    SELECT tbl_temp1.fld_order_id
    FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for an `INSERT  ...  SELECT` statement:

- Prior to MySQL 4.0.1, `INSERT  ...  SELECT` implicitly operates in `IGNORE` mode. As of MySQL 4.0.1, specify `IGNORE` explicitly to ignore records that would cause duplicate-key violations.

- Do not use `DELAYED` with `INSERT  ...  SELECT`.

- Prior to MySQL 4.0.14, the target table of the `INSERT` statement cannot appear in the `FROM` clause of the `SELECT` part of the query. This limitation is lifted in 4.0.14.

- `AUTO_INCREMENT` columns work as usual.

- To ensure that the binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts during `INSERT  ...  SELECT`.

- Currently, you cannot insert into a table and select from the same table in a subquery.

In the values part of `ON DUPLICATE KEY UPDATE` you can refer to column in other tables, as long as you don't use `GROUP BY` in the `SELECT` part. One side effect is that you must qualify non-unique column names in the values part.

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded.

13.2.4.2. `INSERT  DELAYED` Syntax

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL that is very useful if you have clients that can't wait for the `INSERT` to complete. This is a common problem when you use MySQL for logging and you also periodically run `SELECT` and `UPDATE` statements that take a long time to complete. `DELAYED` was introduced in MySQL 3.22.15.

When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using `INSERT DELAYED` is that inserts from many clients are bundled together and written in one block. This is much faster than doing many separate inserts.

There are some constraints on the use of `DELAYED`:

- `INSERT DELAYED` works only with `ISAM`, `MyISAM`, (beginning with MySQL 4.1) `MEMORY`, and `ARCHIVE` tables. For `MyISAM` tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and `INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with `MyISAM`. See Section 14.1, "The `My-ISAM` Storage Engine", Section 14.3, "The `MEMORY` (HEAP) Storage Engine", Section 14.7, "The `ARCHIVE` Storage Engine".

- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. This is enforced as of MySQL 4.0.18. The server ignores `DELAYED` for `INSERT DELAYED ... SELECT` statements.

- The server ignores `DELAYED` for `INSERT DELAYED ... ON DUPLICATE UPDATE` statements.

- Because the statement returns immediately before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value the statement might generate.

- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.

- `DELAYED` is ignored on slave replication servers because it could cause the slave to have different data than the master.

Note that currently the queued rows are held only in memory until they are inserted into the table. This means that if you terminate `mysqld` forcibly (for example, with `kill -9`) or if `mysqld` dies unexpectedly, any queued rows that have not been written to disk are lost!

The following describes in detail what happens when you use the `DELAYED` option to `INSERT` or `REPLACE`. In this description, the "thread" is the thread that received an `INSERT DELAYED` statement and "handler" is the thread that handles all `INSERT DELAYED` statements for a particular table.

- When a thread executes a `DELAYED` statement for a table, a handler thread is created to process all `DELAYED` statements for the table, if no such handler previously exists.

- The thread checks whether the handler has previously acquired a `DELAYED` lock; if not, it tells the handler thread to do so. The `DELAYED` lock can be obtained even if other threads have a `READ` or `WRITE` lock on the table. However, the handler waits for all `ALTER TABLE` locks or `FLUSH TABLES` to ensure that the table structure is up to date.

- The thread executes the `INSERT` statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.

- The client cannot obtain from the server the number of duplicate records or the `AUTO_INCREMENT` value for the resulting row, because the `INSERT` returns before the insert operation has been completed. (If you use the C API, the `mysql_info()` function doesn't return anything meaningful, for the same reason.)

- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.

- After every `delayed_insert_limit` rows are written, the handler checks whether any `SELECT` statements are still pending. If so, it allows these to execute before continuing.

- When the handler has no more rows in its queue, the table is unlocked. If no new `INSERT DELAYED` statements are received within `delayed_insert_timeout` seconds, the handler terminates.

- If more than `delayed_queue_size` rows are pending in a specific handler queue, the thread requesting `INSERT DELAYED` waits until there is room in the queue. This is done to ensure that the `mysqld` server doesn't use all memory for the delayed memory queue.

- The handler thread shows up in the MySQL process list with `delayed_insert` in the `Command` column. It is killed if you execute a `FLUSH TABLES` statement or kill it with `KILL thread_id`. However, before exiting, it first stores all queued rows into the table. During this time it does not accept any new `INSERT` statements from another thread. If you execute an `INSERT DELAYED` statement after this, a new handler thread is created.

Note that this means that `INSERT DELAYED` statements have higher priority than normal `IN-`

SERT statements if there is an `INSERT DELAYED` handler running. Other update statements have to wait until the `INSERT DELAYED` queue is empty, someone terminates the handler thread (with `KILL thread_id`), or someone executes `FLUSH TABLES`.

- The following status variables provide information about `INSERT DELAYED` statements:

Status Variable	Meaning
`Delayed_insert_threads`	Number of handler threads
`Delayed_writes`	Number of rows written with `INSERT DELAYED`
`Not_flushed_delayed_rows`	Number of rows waiting to be written

You can view these variables by issuing a `SHOW STATUS` statement or by executing a `mysqladmin extended-status` command.

Note that `INSERT DELAYED` is slower than a normal `INSERT` if the table is not in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it!

13.2.5. `LOAD DATA INFILE` Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name.txt'
    [REPLACE | IGNORE]
    INTO TABLE tbl_name
    [FIELDS
        [TERMINATED BY 'string']
        [[OPTIONALLY] ENCLOSED BY 'char']
        [ESCAPED BY 'char' ]
    ]
    [LINES
        [STARTING BY 'string']
        [TERMINATED BY 'string']
    ]
    [IGNORE number LINES]
    [(col_name_or_user_var,...)]
    [SET col_name = expr,...)]
```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. The filename must be given as a literal string.

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, Section 7.2.16, "Speed of `INSERT` Statements".

As of MySQL 4.1, the character set indicated by the `character_set_database` system variable is used to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect input interpretation.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See Section 8.10, "mysqlimport — A Data Import Program".

If you specify the `LOW_PRIORITY` keyword, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table.

If you specify the `CONCURRENT` keyword with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), then other threads can retrieve data

from the table while `LOAD DATA` is executing. Using this option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

If the `LOCAL` keyword is specified, it is interpreted with respect to the client end of the connection:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full pathname to specify its exact location. If given as a relative pathname, the name is interpreted relative to the directory in which the client program was started.

- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server.

`LOCAL` is available in MySQL 3.22.6 or later.

When locating files on the server host, the server uses the following rules:

- If an absolute pathname is given, the server uses the pathname as is.

- If a relative pathname with one or more leading components is given, the server searches for the file relative to the server's data directory.

- If a filename with no leading components is given, the server looks for the file in the database directory of the default database.

Note that these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the same file named as `myfile.txt` is read from the database directory of the default database. For example, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1` because `db1` is the current database, even though the statement explicitly loads the file into a table in the `db2` database:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Note that Windows pathnames are specified using forward slashes rather than backslashes. If you do use backslashes, you must double them.

For security reasons, when reading text files located on the server, the files must either reside in the database directory or be readable by all. Also, to use `LOAD DATA INFILE` on server files, you must have the `FILE` privilege.

See Section 5.6.3, "Privileges Provided by MySQL".

Using `LOCAL` is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE` privilege to load local files.

As of MySQL 3.23.49 and MySQL 4.0.2 (4.0.13 on Windows), `LOCAL` works only if your server and your client both have been enabled to allow it. For example, if `mysqld` was started with `--local-infile=0`, `LOCAL` does not work. See Section 5.5.4, "Security Issues with `LOAD DATA LOCAL`".

If you need `LOAD DATA` to read from a pipe, you can use the following technique (here we load the listing of the '/' directory into a table):

```
mkfifo /mysql/db/x/x
chmod 666 /mysql/db/x/x
find / -ls > /mysql/db/x/x
mysql -e "LOAD DATA INFILE 'x' INTO TABLE x" x
```

If you are using a version of MySQL older than 3.23.25, you can use this technique only with `LOAD DATA LOCAL INFILE`.

If you are using MySQL before Version 3.23.24, you can't read from a FIFO with `LOAD DATA INFILE`. If you need to read from a FIFO (for example, the output from `gunzip`), use `LOAD DATA LOCAL INFILE` instead.

The `REPLACE` and `IGNORE` keywords control handling of input records that duplicate existing records on unique key values.

If you specify `REPLACE`, input rows replace existing rows (in other words, rows that have the same value for a primary or unique index as an existing row). See Section 13.2.6, "`REPLACE` Syntax".

If you specify `IGNORE`, input rows that duplicate an existing row on a unique key value are skipped. If you don't specify either option, the behavior depends on whether or not the `LOCAL` keyword is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

If you want to ignore foreign key constraints during the load operation, you can issue a `SET FOR-EIGN_KEY_CHECKS=0` statement before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all non-unique indexes are created in a separate batch (as for `REPAIR TABLE`). This normally makes `LOAD DATA INFILE` much faster when you have many indexes. Normally this is very fast, but in some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE .. DISABLE KEYS` before loading the file into the table and using `ALTER TABLE .. ENABLE KEYS` to re-create the indexes after loading the file. See Section 7.2.16, "Speed of `INSERT` Statements".

`LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. See Section 13.2.7, "`SELECT` Syntax". To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you don't specify a `FIELDS` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
```

If you don't specify a `LINES` clause, the default is the same as if you had written this:

```
LINES TERMINATED BY '\n' STARTING BY ''
```

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.

- Do not skip over any line prefix.

- Break lines into fields at tabs.

- Do not expect fields to be enclosed within any quoting characters.

- Interpret occurrences of tab, newline, or '\' preceded by '\' as literal characters that are part of field values.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.

- Do not enclose fields within any quoting characters.

- Use '\' to escape instances of tab, newline, or '\' that occur within field values.

- Write newlines at the ends of lines.

Note that to write `FIELDS ESCAPED BY '\\'`, you must specify two backslashes for the value to be read as a single backslash.

Note: If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix (and anything before it). If a line doesn't include the prefix, the entire line is skipped. **Note** that `prefix_string` may be in the middle of the line!

Example:

```
mysql> LOAD DATA INFILE '/tmp/test.txt'
    -> INTO TABLE test LINES STARTING BY "xxx";
```

With this you can read in a file that contains something like:

```
xxx"Row",1
something xxx"Row",2
```

And just get the data (`"row",1`) and (`"row",2`).

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
mysql> LOAD DATA INFILE '/tmp/test.txt'
    -> INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA INFILE` does not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
mysql> SELECT * INTO OUTFILE 'data.txt'
    ->         FIELDS TERMINATED BY ','
    ->         FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
mysql> LOAD DATA INFILE 'data.txt' INTO TABLE table2
    ->         FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown here, it wouldn't work because it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
mysql> LOAD DATA INFILE 'data.txt' INTO TABLE table2
    ->              FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources, too. For example, a file in dBASE format has fields separated by commas and enclosed within double quotes. If lines in the file are terminated by newlines, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
mysql> LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
    ->              FIELDS TERMINATED BY ',' ENCLOSED BY '"'
    ->              LINES TERMINATED BY '\n';
```

Any of the field- or line-handling options can specify an empty string (`''`). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```
mysql> CREATE TABLE jokes
    ->      (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->       joke TEXT NOT NULL);
mysql> LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
    ->      FIELDS TERMINATED BY ''
    ->      LINES TERMINATED BY '\n%%\n' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (`SELECT ... INTO OUTFILE`), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a \", quote and comma","102.20"
```

If you specify `OPTIONALLY`, the `ENCLOSED BY` character is used only to enclose values in columns that have a string data type (such as `CHAR`, `BINARY`, `TEXT`, or `ENUM`):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Note that occurrences of the `ENCLOSED BY` character within a field value are escaped by prefixing them with the `ESCAPED BY` character. Also note that if you specify an empty `ESCAPED BY` value, it is possible to generate output that cannot be read properly by `LOAD DATA INFILE`. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the ENCLOSED BY character, if present, is stripped from the ends of field values. (This is true whether or not OPTIONALLY is specified; OPTIONALLY has no effect on input interpretation.) Occurrences of the ENCLOSED BY character preceded by the ESCAPED BY character are interpreted as part of the current field value.

If the field begins with the ENCLOSED BY character, instances of that character are recognized as terminating a field value only if followed by the field or line TERMINATED BY sequence. To avoid ambiguity, occurrences of the ENCLOSED BY character within a field value can be doubled and are interpreted as a single instance of the character. For example, if ENCLOSED BY '"' is specified, quotes are handled as shown here:

```
"The ""BIG"" boss"  -> The "BIG" boss
The "BIG" boss       -> The "BIG" boss
The ""BIG"" boss     -> The ""BIG"" boss
```

FIELDS ESCAPED BY controls how to write or read special characters. If the FIELDS ESCAPED BY character is not empty, it is used to prefix the following characters on output:

- The FIELDS ESCAPED BY character

- The FIELDS [OPTIONALLY] ENCLOSED BY character

- The first character of the FIELDS TERMINATED BY and LINES TERMINATED BY values

- ASCII 0 (what is actually written following the escape character is ASCII '0', not a zero-valued byte)

If the FIELDS ESCAPED BY character is empty, no characters are escaped and NULL is output as NULL, not \N. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

For input, if the FIELDS ESCAPED BY character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. The exceptions are an escaped '0' or 'N' (for example, \0 or \N if the escape character is '\'). These sequences are interpreted as ASCII NUL (a zero-valued byte) and NULL. The rules for NULL handling are described later in this section.

For more information about '\'-escape syntax, see Section 9.1, "Literal Values".

In certain cases, field- and line-handling options interact:

- If LINES TERMINATED BY is an empty string and FIELDS TERMINATED BY is non-empty, lines are also terminated with FIELDS TERMINATED BY.

- If the FIELDS TERMINATED BY and FIELDS ENCLOSED BY values are both empty (''), a fixed-row (non-delimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are written and read using the "display" widths of the columns. For example, if a column is declared as INT(7), values for the column are written using seven-character fields. On input, values for the column are obtained by reading seven characters.

  LINES TERMINATED BY is still used to separate lines. If a line doesn't contain all fields, the rest of the columns are set to their default values. If you don't have a line terminator, you should set this to ''. In this case, the text file must contain all fields for each row.

  Fixed-row format also affects handling of NULL values, as described later. Note that fixed-size format does not work if you are using a multi-byte character set.

Handling of NULL values varies according to the FIELDS and LINES options in use:

- For the default FIELDS and LINES values, NULL is written as a field value of \N for output, and a field value of \N is read as NULL for input (assuming that the ESCAPED BY character is '\').

- If FIELDS ENCLOSED BY is not empty, a field containing the literal word NULL as its value is read as a NULL value. This differs from the word NULL enclosed within FIELDS EN-CLOSED BY characters, which is read as the string 'NULL'.

- If FIELDS ESCAPED BY is empty, NULL is written as the word NULL.

- With fixed-row format (which happens when FIELDS TERMINATED BY and FIELDS EN-CLOSED BY are both empty), NULL is written as an empty string. Note that this causes both NULL values and empty strings in the table to be indistinguishable when written to the file because they are both written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

Some cases are not supported by LOAD DATA INFILE:

- Fixed-size rows (FIELDS TERMINATED BY and FIELDS ENCLOSED BY both empty) and BLOB or TEXT columns.

- If you specify one separator that is the same as or a prefix of another, LOAD DATA INFILE won't be able to interpret the input properly. For example, the following FIELDS clause would cause problems:

```
FIELDS TERMINATED BY '"' ENCLOSED BY '"'
```

- If FIELDS ESCAPED BY is empty, a field value that contains an occurrence of FIELDS EN-CLOSED BY or LINES TERMINATED BY followed by the FIELDS TERMINATED BY value causes LOAD DATA INFILE to stop reading a field or line too early. This happens because LOAD DATA INFILE cannot properly determine where the field or line value ends.

The following example loads all columns of the persondata table:

```
mysql> LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the LOAD DATA INFILE statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
mysql> LOAD DATA INFILE 'persondata.txt'
    ->             INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match up input fields with table columns.

Before MySQL 5.0.3, the column list must contain only names of columns in the table being loaded, and the SET clause is not supported. As of MySQL 5.0.3, the column list can contain either column names or user variables, and the SET clause is supported. This enables you to assign input values to user variables, and then perform transformations on those values before assigning the result to columns.

User variables in the SET clause can be used in several ways. The following example uses the first column in the data file directly for the value of t1.column1, and assigns the second column to a

user variable that is subjected to a division operation before being used for the value of `t2.column2`:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. THe following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of the assignment operator.

- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.

- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.

- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in Section 13.1.5, "`CREATE TABLE` Syntax".

An empty field value is interpreted differently than if the field value is missing:

- For string types, the column is set to the empty string.

- For numeric types, the column is set to `0`.

- For date and time types, the column is set to the appropriate "zero" value for the type. See Section 11.3, "Date and Time Types".

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`), or (for the first `TIMESTAMP` column only) if the `TIMESTAMP` column is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you can't use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings!

When the `LOAD DATA INFILE` statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See Section 23.2.3.32, "`mysql_info()`".

Warnings occur under the same circumstances as when values are inserted via the `INSERT` statement (see Section 13.2.4, "`INSERT` Syntax"), except that `LOAD DATA INFILE` also generates warnings when there are too few or too many fields in the input row. The warnings are not stored anywhere; the number of warnings can be used only as an indication of whether everything went well.

From MySQL 4.1.1 on, you can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See Section 13.5.4.22, "`SHOW WARNINGS` Syntax".

Before MySQL 4.1.1, only a warning count is available to indicate that something went wrong. If you get warnings and want to know exactly why you got them, one way to do this is to dump the table into another file using `SELECT ... INTO OUTFILE` and compare the file to your original input file.

13.2.6. `REPLACE` Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [(col_name,...)]
    VALUES ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name
    SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [(col_name,...)]
    SELECT ...
```

`REPLACE` works exactly like `INSERT`, except that if an old record in the table has the same value as a new record for a `PRIMARY KEY` or a `UNIQUE` index, the old record is deleted before the new record is inserted. See Section 13.2.4, "`INSERT` Syntax".

Note that unless the table has a `PRIMARY KEY` or `UNIQUE` index, using a `REPLACE` statement makes no sense. It becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You can't refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

To be able to use `REPLACE`, you must have `INSERT` and `DELETE` privileges for the table.

The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

Currently, you cannot replace into a table and select from the same table in a subquery.

Here follows in more detail the algorithm that is used (it is also used with `LOAD DATA ... RE-PLACE`):

1. Try to insert the new row into the table

2. While the insertion fails because a duplicate-key error occurs for a primary or unique key:

    a. Delete from the table the conflicting row that has the duplicate key value

    b. Try again to insert the new row into the table

13.2.7. `SELECT` Syntax

```
SELECT
    [ALL | DISTINCT | DISTINCTROW ]
      [HIGH_PRIORITY]
      [STRAIGHT_JOIN]
      [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
      [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
    select_expr, ...
    [INTO OUTFILE 'file_name' export_options
      | INTO DUMPFILE 'file_name']
    [FROM table_references
      [WHERE where_definition]
      [GROUP BY {col_name | expr | position}
        [ASC | DESC], ... [WITH ROLLUP]]
      [HAVING where_definition]
      [ORDER BY {col_name | expr | position}
        [ASC | DESC] , ...]
      [LIMIT {[offset,] row_count | row_count OFFSET offset}]
      [PROCEDURE procedure_name(argument_list)]
      [FOR UPDATE | LOCK IN SHARE MODE]]
```

`SELECT` is used to retrieve rows selected from one or more tables. Support for `UNION` statements and subqueries is available as of MySQL 4.0 and 4.1, respectively. See Section 13.2.7.2, "`UNION` Syntax" and Section 13.2.8, "Subquery Syntax".

- Each *select_expr* indicates a column you want to retrieve.

- *table_references* indicates the table or tables from which to retrieve rows. Its syntax is described in Section 13.2.7.1, "JOIN Syntax".

- *where_definition* consists of the keyword WHERE followed by an expression that indicates the condition or conditions that rows must satisfy to be selected.

SELECT can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
        -> 2
```

All clauses used must be given in exactly the order shown in the syntax description. For example, a HAVING clause must come after any GROUP BY clause and before any ORDER BY clause.

-
    A *select_expr* can be given an alias using AS alias_name. The alias is used as the expression's column name and can be used in GROUP BY, ORDER BY, or HAVING clauses. For example:

    ```
    mysql> SELECT CONCAT(last_name,', ',first_name) AS full_name
        -> FROM mytable ORDER BY full_name;
    ```

    The AS keyword is optional when aliasing a *select_expr*. The preceding example could have been written like this:

    ```
    mysql> SELECT CONCAT(last_name,', ',first_name) full_name
        -> FROM mytable ORDER BY full_name;
    ```

    Because the AS is optional, a subtle problem can occur if you forget the comma between two *select_expr* expressions: MySQL interprets the second as an alias name. For example, in the following statement, columnb is treated as an alias name:

    ```
    mysql> SELECT columna columnb FROM mytable;
    ```

- It is not allowable to use a column alias in a WHERE clause, because the column value might not yet be determined when the WHERE clause is executed. See Section A.5.4, "Problems with Column Aliases".

- The FROM *table_references* clause indicates the tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.7.1, "JOIN Syntax". For each table specified, you can optionally specify an alias.

    ```
    tbl_name [[AS] alias]
        [[USE INDEX (key_list)]
          │ [IGNORE INDEX (key_list)]
          │ [FORCE INDEX (key_list)]]
    ```

    The use of USE INDEX, IGNORE INDEX, FORCE INDEX to give the optimizer hints about how to choose indexes is described in Section 13.2.7.1, "JOIN Syntax".

    In MySQL 4.0.14, you can use SET max_seeks_for_key=*value* as an alternative way to force MySQL to prefer key scans instead of table scans.

- You can refer to a table within the current database as *tbl_name* (within the current database),

or as *db_name.tbl_name* to explicitly specify a database. You can refer to a column as *col_name*, *tbl_name.col_name*, or *db_name.tbl_name.col_name*. You need not specify a *tbl_name* or *db_name.tbl_name* prefix for a column reference unless the reference would be ambiguous. See Section 9.2, "Database, Table, Index, Column, and Alias Names" for examples of ambiguity that require the more explicit column reference forms.

- From MySQL 4.1.0 on, you are allowed to specify DUAL as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
        -> 2
```

DUAL is purely a compatibility feature. Some other servers require this syntax.

- A table reference can be aliased using *tbl_name* AS *alias_name* or *tbl_name alias_name*:

```
mysql> SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
    ->        WHERE t1.name = t2.name;
mysql> SELECT t1.name, t2.salary FROM employee t1, info t2
    ->        WHERE t1.name = t2.name;
```

- In the WHERE clause, you can use any of the functions that MySQL supports, except for aggregate (summary) functions. See Chapter 12, *Functions and Operators*.

- Columns selected for output can be referred to in ORDER BY and GROUP BY clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
mysql> SELECT college, region, seed FROM tournament
    ->        ORDER BY region, seed;
mysql> SELECT college, region AS r, seed AS s FROM tournament
    ->        ORDER BY r, s;
mysql> SELECT college, region, seed FROM tournament
    ->        ORDER BY 2, 3;
```

To sort in reverse order, add the DESC (descending) keyword to the name of the column in the ORDER BY clause that you are sorting by. The default is ascending order; this can be specified explicitly using the ASC keyword.

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use GROUP BY, output rows are sorted according to the GROUP BY columns as if you had an ORDER BY for the same columns. MySQL has extended the GROUP BY clause as of version 3.23.34 so that you can also specify ASC and DESC after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC
```

- MySQL extends the use of GROUP BY to allow you to select fields that are not mentioned in the GROUP BY clause. If you are not getting the results you expect from your query, please read the GROUP BY description. See Section 12.10, "Functions and Modifiers for Use with GROUP BY Clauses".

- As of MySQL 4.1.1, GROUP BY allows a WITH ROLLUP modifier. See Section 12.10.2, "GROUP BY Modifiers".

- The HAVING clause is applied nearly last, just before items are sent to the client, with no optimization. (LIMIT is applied after HAVING.)

Before MySQL 5.0.2, a HAVING clause can refer to any column or alias named in a *se-*

lect_expr in the `SELECT` list or in outer subqueries, and to aggregate functions. Standard SQL requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. To accommodate both standard SQL and the MySQL-specific behavior of being able to refer columns in the `SELECT` list, MySQL 5.0.2 and up allows `HAVING` to refer to columns in the `SELECT` list, columns in the `GROUP BY` clause, columns in outer subqueries, and to aggregate functions.

For example, the following statement works in MySQL 5.0.2 but produces an error for earlier versions:

```
mysql> SELECT COUNT(*) FROM t GROUP BY col1 HAVING col1 = 2;
```

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used both as an alias and as a column name:

```
mysql> SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so that if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preferences is given to the column in the `GROUP BY` column.

- Don't use `HAVING` for items that should be in the `WHERE` clause. For example, do not write this:

```
mysql> SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
mysql> SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

```
mysql> SELECT user, MAX(salary) FROM users
    ->     GROUP BY user HAVING MAX(salary)>10;
```

However, that does not work in older MySQL servers (before version 3.22.5). Instead, you can use a column alias in the select list and refer to the alias in the `HAVING` clause:

```
mysql> SELECT user, MAX(salary) AS max_salary FROM users
    ->     GROUP BY user HAVING max_salary>10;
```

- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be non-negative integer constants (except when using prepared statements).

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
mysql> SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT` *row_count* `OFFSET` *offset* syntax.

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
mysql> SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
mysql> SELECT * FROM tbl LIMIT 5;     # Retrieve first 5 rows
```

In other words, `LIMIT n` is equivalent to `LIMIT 0,n`.

For prepared statements, you can use placeholders (supported as of MySQL version 5.0.7). The following statements will return one row from the `tbl` table:

```
mysql> SET @a=1;
mysql> PREPARE STMT FROM "SELECT * FROM tbl LIMIT ?";
mysql> EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
mysql> SET @skip=1; SET @numrows=5;
mysql> PREPARE STMT FROM "SELECT * FROM tbl LIMIT ?, ?";
mysql> EXECUTE STMT USING @skip, @numrows;
```

•

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. The file cannot currently exist, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed.

The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table on the server machine. If you want to create the resulting file on some client host other than the server host, you can't use `SELECT ... INTO OUTFILE`. In that case, you should instead use some command like `mysql -e "SELECT ..." > file_name` on the client host to generate the file.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`; the syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See Section 13.2.5, "`LOAD DATA INFILE` Syntax".

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:

- The `FIELDS ESCAPED BY` character

- The `FIELDS [OPTIONALLY] ENCLOSED BY` character

- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values

- ASCII `0` (what is actually written following the escape character is ASCII '0', not a zero-valued byte)

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

The reason for the above is that you *must* escape any `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters to reliably be able to read the file back. ASCII NUL is escaped to make it easier to view with some pagers.

The resulting file doesn't have to conform to SQL syntax, so nothing else need be escaped.

Here is an example that produces a file in the comma-separated values format used by many pro-

grams:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.text'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
FROM test_table;
```

• If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.

• **Note**: Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server can't create a file that is owned by anyone other than the user it's running as (you should never run `mysqld` as `root`). The file thus must be world-writable so that you can manipulate its contents.

• A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see Section 25.3.1, "Procedure Analyse".

• If you use `FOR UPDATE` on a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that prevents other transactions from updating or deleting the examined rows. See Section 15.11.5, "Locking Reads `SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE`".

Following the `SELECT` keyword, you can give a number of options that affect the operation of the statement.

The `ALL`, `DISTINCT`, and `DISTINCTROW` options specify whether duplicate rows should be returned. If none of these options are given, the default is `ALL` (all matching rows are returned). `DISTINCT` and `DISTINCTROW` are synonyms and specify that duplicate rows in the result set should be removed.

`HIGH_PRIORITY`, `STRAIGHT_JOIN`, and options beginning with `SQL_` are MySQL extensions to standard SQL.

•

    `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free.

    `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

• `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in non-optimal order. See Section 7.2.1, "`EXPLAIN` Syntax (Get Information About a `SELECT`)". `STRAIGHT_JOIN` also can be used in the *table_references* list. See Section 13.2.7.1, "`JOIN` Syntax".

• `SQL_BIG_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows. In this case, MySQL directly uses disk-based temporary tables if needed. MySQL also, in this case, prefers sorting to using a temporary table with a key on the `GROUP BY` elements.

• `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client.

• `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that

the result set is small. In this case, MySQL uses fast temporary tables to store the resulting table instead of using sorting. In MySQL 3.23 and up, this shouldn't normally be needed.

- `SQL_CALC_FOUND_ROWS` (available in MySQL 4.0.0 and up) tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See Section 12.9.3, "Information Functions".

  Before MySQL 4.1.0, this option does not work with `LIMIT 0`, which is optimized to return instantly (resulting in a row count of 0). See Section 7.2.14, "How MySQL Optimizes `LIMIT`".

- `SQL_CACHE` tells MySQL to store the query result in the query cache if you are using a `query_cache_type` value of 2 or `DEMAND`. For a query that uses `UNION` or subqueries, this option takes effect to be used in any `SELECT` of the query. See Section 5.12, "The MySQL Query Cache".

- `SQL_NO_CACHE` tells MySQL not to store the query result in the query cache. See Section 5.12, "The MySQL Query Cache". For a query that uses `UNION` or subqueries, this option takes effect to be used in any `SELECT` of the query.

13.2.7.1. `JOIN` Syntax

Before MySQL 5.0, MySQL supports the following `JOIN` syntaxes for the *table_references* part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_reference, table_reference
table_reference [INNER | CROSS] JOIN table_reference [join_condition]
table_reference STRAIGHT_JOIN table_reference
table_reference LEFT [OUTER] JOIN table_reference join_condition
table_reference NATURAL [LEFT [OUTER]] JOIN table_reference
{ ON table_reference LEFT OUTER JOIN table_reference
    ON conditional_expr }
table_reference RIGHT [OUTER] JOIN table_reference join_condition
table_reference NATURAL [RIGHT [OUTER]] JOIN table_reference
```

table_reference is defined as:

```
tbl_name [[AS] alias]
    [[USE INDEX (key_list)]
      │ [IGNORE INDEX (key_list)]
      │ [FORCE INDEX (key_list)]]
```

join_condition is defined as:

```
ON conditional_expr | USING (column_list)
```

As of MySQL 5.0.1, supported `JOIN` syntax is as follows:

```
table_references:
    table_reference [, table_reference] …

table_reference:
    table_factor
  | join_table

table_factor:
    tbl_name [[AS] alias]
        [[USE INDEX (key_list)]
          │ [IGNORE INDEX (key_list)]
          │ [FORCE INDEX (key_list)]]
  | ( table_references )
  | { OJ table_reference LEFT OUTER JOIN table_reference
```

```
        ON conditional_expr }

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON condition
  | table_reference LEFT [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [LEFT [OUTER]] JOIN table_factor
  | table_reference RIGHT [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [RIGHT [OUTER]] JOIN table_factor
```

A table reference is also known as as join expression.

The syntax of `table_factor` is extended in comparison with the SQL Standard. The latter accepts only `table_reference`, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of `table_reference` items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
                 ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to :

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
                 ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other. In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause, `CROSS JOIN` is used otherwise.

In versions of MySQL prior to 5.0.1, parentheses in `table_references` were just omitted and all join operations were grouped to the left. In general, parentheses can be ignored in join expressions containing only inner join operations. As of 5.0.1, nested joins are allowed (see Section 7.2.10, "How MySQL Optimizes Nested Joins").

You should generally not have any conditions in the `ON` part that are used to restrict which rows you want in the result set, but rather specify these conditions in the `WHERE` clause. There are exceptions to this rule.

Note that `INNER JOIN` syntax allows a `join_condition` only from MySQL 3.23.17 on. The same is true for `JOIN` and `CROSS JOIN` only as of MySQL 4.0.11.

The { OJ ... LEFT OUTER JOIN ...} syntax shown in the preceding list exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
mysql> SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
    ->        WHERE t1.name = t2.name;
mysql> SELECT t1.name, t2.salary FROM employee t1, info t2
    ->        WHERE t1.name = t2.name;
```

- The `ON` conditional is any conditional expression of the form that can be used in a `WHERE` clause.

- If there is no matching record for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find records in a table that have no counterpart in another table:

```
mysql> SELECT table1.* FROM table1
    ->          LEFT JOIN table2 ON table1.id=table2.id
    ->          WHERE table2.id IS NULL;
```

This example finds all rows in table1 with an id value that is not present in table2 (that is, all rows in table1 with no corresponding row in table2). This assumes that table2.id is declared NOT NULL. See Section 7.2.9, "How MySQL Optimizes LEFT JOIN and RIGHT JOIN".

- The USING (column_list) clause names a list of columns that must exist in both tables. The following two clauses are semantically identical:

```
a LEFT JOIN b USING (c1,c2,c3)
a LEFT JOIN b ON a.c1=b.c1 AND a.c2=b.c2 AND a.c3=b.c3
```

- The NATURAL [LEFT] JOIN of two tables is defined to be semantically equivalent to an INNER JOIN or a LEFT JOIN with a USING clause that names all columns that exist in both tables.

-
  INNER JOIN and , (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table are joined to all rows in the second table).

- RIGHT JOIN works analogously to LEFT JOIN. To keep code portable across databases, it's recommended to use LEFT JOIN instead of RIGHT JOIN.

-
  STRAIGHT_JOIN is identical to JOIN, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer puts the tables in the wrong order.

As of MySQL 3.23.12, you can give hints about which index MySQL should use when retrieving information from a table. By specifying USE INDEX (key_list), you can tell MySQL to use only one of the possible indexes to find rows in the table. The alternative syntax IGNORE INDEX (key_list) can be used to tell MySQL to not use some particular index. These hints are useful if EXPLAIN shows that MySQL is using the wrong index from the list of possible indexes.

From MySQL 4.0.9 on, you can also use FORCE INDEX. This acts likes USE INDEX (key_list) but with the addition that a table scan is assumed to be *very* expensive. In other words, a table scan is only used if there is no way to use one of the given indexes to find rows in the table.

USE KEY, IGNORE KEY, and FORCE KEY are synonyms for USE INDEX, IGNORE INDEX, and FORCE INDEX.

Note: USE INDEX, IGNORE INDEX, and FORCE INDEX only affect which indexes are used when MySQL decides how to find rows in the table and how to do the join. They do not affect whether an index is used when resolving an ORDER BY or GROUP BY.

Some join examples:

```
mysql> SELECT * FROM table1,table2 WHERE table1.id=table2.id;
mysql> SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id;
mysql> SELECT * FROM table1 LEFT JOIN table2 USING (id);
mysql> SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id
    ->          LEFT JOIN table3 ON table2.id=table3.id;
mysql> SELECT * FROM table1 USE INDEX (key1,key2)
    ->          WHERE key1=1 AND key2=2 AND key3=3;
mysql> SELECT * FROM table1 IGNORE INDEX (key3)
    ->          WHERE key1=1 AND key2=2 AND key3=3;
```

See Section 7.2.9, "How MySQL Optimizes `LEFT JOIN` and `RIGHT JOIN`".

13.2.7.2. `UNION` Syntax

```
SELECT ...
UNION [ALL | DISTINCT]
SELECT ...
  [UNION [ALL | DISTINCT]
   SELECT ...]
```

`UNION` is used to combine the result from many `SELECT` statements into one result set. `UNION` is available from MySQL 4.0.0 on.

Selected columns listed in corresponding positions of each `SELECT` statement should have the same type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.) The column names used in the first `SELECT` statement are used as the column names for the results returned.

The `SELECT` statements are normal select statements, but with the following restrictions:

• Only the last `SELECT` statement can have `INTO OUTFILE`.

• `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`. If you specify it for the first `SELECT`, it has no effect. If you specify it for any subsequent `SELECT` statements, a syntax error results.

If you don't use the keyword `ALL` for the `UNION`, all returned rows are unique, as if you had done a `DISTINCT` for the total result set. If you specify `ALL`, you get all matching rows from all the used `SELECT` statements.

The `DISTINCT` keyword is an optional word (introduced in MySQL 4.0.17). It does nothing, but is allowed in the syntax as required by the SQL standard.

Before MySQL 4.1.2, you cannot mix `UNION ALL` and `UNION DISTINCT` in the same query. If you use `ALL` for one `UNION`, it is used for all of them. As of MySQL 4.1.2, mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

If you want to use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM tbl_name WHERE a=10 AND B=1)
UNION
(SELECT a FROM tbl_name WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`, or else refer to the column in the `ORDER BY` using its column position. (An alias is preferable because use of column positions is deprecated.)

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM tbl_name WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM tbl_name WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

ORDER BY for individual SELECT statements within parentheses only has an effect when combined with LIMIT. Otherwise, the ORDER BY is optimized away.

The types and lengths of the columns in the result set of a UNION take into account the values retrieved by all the SELECT statements. Before MySQL 4.1.1, a limitation of UNION is that only the values from the first SELECT are used to determine result column types and lengths. This could result in value truncation if, for example, the first SELECT retrieves shorter values than the second SELECT:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+---------------+
| REPEAT('a',1) |
+---------------+
| a             |
| b             |
+---------------+
```

That limitation has been removed as of MySQL 4.1.1:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+---------------+
| REPEAT('a',1) |
+---------------+
| a             |
| bbbbbbbbbb    |
+---------------+
```

13.2.8. Subquery Syntax

A subquery is a SELECT statement inside another statement.
